History

ABOUT US

DYWIDAG-Systems International (DSI) is a globally leading system supplier of innovative technologies for the construction industry.

TRADITION

The long tradition of DSI reaches back as far as 1865 – the founding year of the German construction firm, Dyckerhoff & Widmann AG (DYWIDAG). DSI was founded in the year 1979 to market DYWIDAG Systems and technical know-how around the world and to develop innovative systems resulting from its own R&D activities.

DSI TECHNOLOGY

In more than 50 countries and at 15 regional manufacturing sites, DSI Construction develops, produces and supplies high quality systems such as DYWIDAG Post-Tensioning Systems, Geotechnical Systems and "Concrete Accessories". In accordance with our slogan "*Local Presence – Global Competence*", more than 1,400 specialized and experienced DSI employees ensure that DSI's technologies and know-how are available around the world. DSI offers quality on all levels – quality that is characterized by creativity, reliability and profitability.

COMPREHENSIVE SERVICES

Our comprehensive services include the conception, design, planning and installation of its systems as well as quality management and on site supervision.

RESEARCH & DEVELOPMENT

Continued investments in Research & Development and the resulting patent applications sustainably strengthen the know-how available within the DSI Construction Group. By offering innovative solutions in accordance with superior quality standards, we fulfill the constantly changing requirements of our target markets. It is our declared aim to always be one step ahead.

CLIENT ORIENTATION

The needs and requirements of clients and business partners are always of paramount importance. Our company is characterized by reliability, trust and cooperation based on partnership. We offer our clients the advantages of an international system supplier with a product range that is tailored to suit individual requirements.

CERTIFICATIONS & INTERNATIONAL ORGANIZATIONS

International organizations, trade associations and standards committees are becoming more important in times in which products and services seem more and more interchangeable. Organizations and trade associations are cross-linked on a global basis and promote the exchange of technology and know-how across borders. We are an active member in many International Organizations to drive technical developments. In April 2016, DSI received a general technical approval for DYNA Grip® Multistrand Stay Cables for Stay Cable Bridges. It is the world's first approval to regulate Multistrand Stay Cable Systems.

1994
Odawara Blueway Bridge, Odawara, Japan

MILESTONES

DYWIDAG Post-Tensioning Systems and Stay Cable Systems are world renowned for reliability and performance; they are perfectly suitable for all applications in post-tensioned construction. They embrace the whole spectrum from bridge construction and buildings to civil applications – both above and below ground.

In addition to traditional post-tensioning systems with bars, DSI offers a complete product line in strand post-tensioning (bonded, unbonded and external) as well as stay-cable systems to fulfill the changing requirements in the industry today and tomorrow.

As a further development of the first cable stayed bridges in the 60's and 70's of the last century, new systems were introduced into the market considering new materials and increasing requirements on modern infrastructures.

The application of DSI's stay cable system for the Odawara Blueway Bridge (Japan) in 1994 – which is known as the first extradosed bridge in the world – as well as for Kap Shui Mun Bridge (Hongkong) in 1995 are two outstanding milestones in DSI's stay cable history.

Established in 2000 and still used today, the DYNA Grip® System already took into account the requirements for modern cable systems at the turn of the millennium. Our stay cable systems have always combined the highest safety and reliability standards with excellent economical efficiency in their research and development.

Dependable corrosion protection methods, damper design, fire protection, vibration measurements and the recently developed DYNA Force® monitoring system significantly contribute to the longevity of modern construction and cable hardening for mitigating multiple threat scenarios (vandalism, fire, blasts etc.).

DYNA Grip® Stay Cable System

The DYNA Grip® Stressing Anchorage consists of an anchor block in which the strands are anchored by high fatigue 3 part-wedges. A ring nut is threaded onto the anchor block to transmit the cable force into the structure via the bearing plate. A steel pipe which incorporates bending and sealing provisions for the strands is part of the anchor block. A non-adjustable anchorage with the same provisions for bending and sealing of the strands can be placed at the dead-end side.

REPLACEABILITY

Exchange of single strands including PE-coating through anchorage - no interruption of traffic

LEAK TIGHTNESS

Gap between threads is filled with corrosion protection compound for improved tightness

EXCELLENT DURABILITY

A watertight and adjustable sealing unit and strands with PE-sheathing up to the wedge meet highest demands. No deviation of strands in the wedge gripping zone

HIGH FATIGUE CAPACITY

Compliance with international fib and PTI standards

HIGH FATIGUE PERFORMANCE

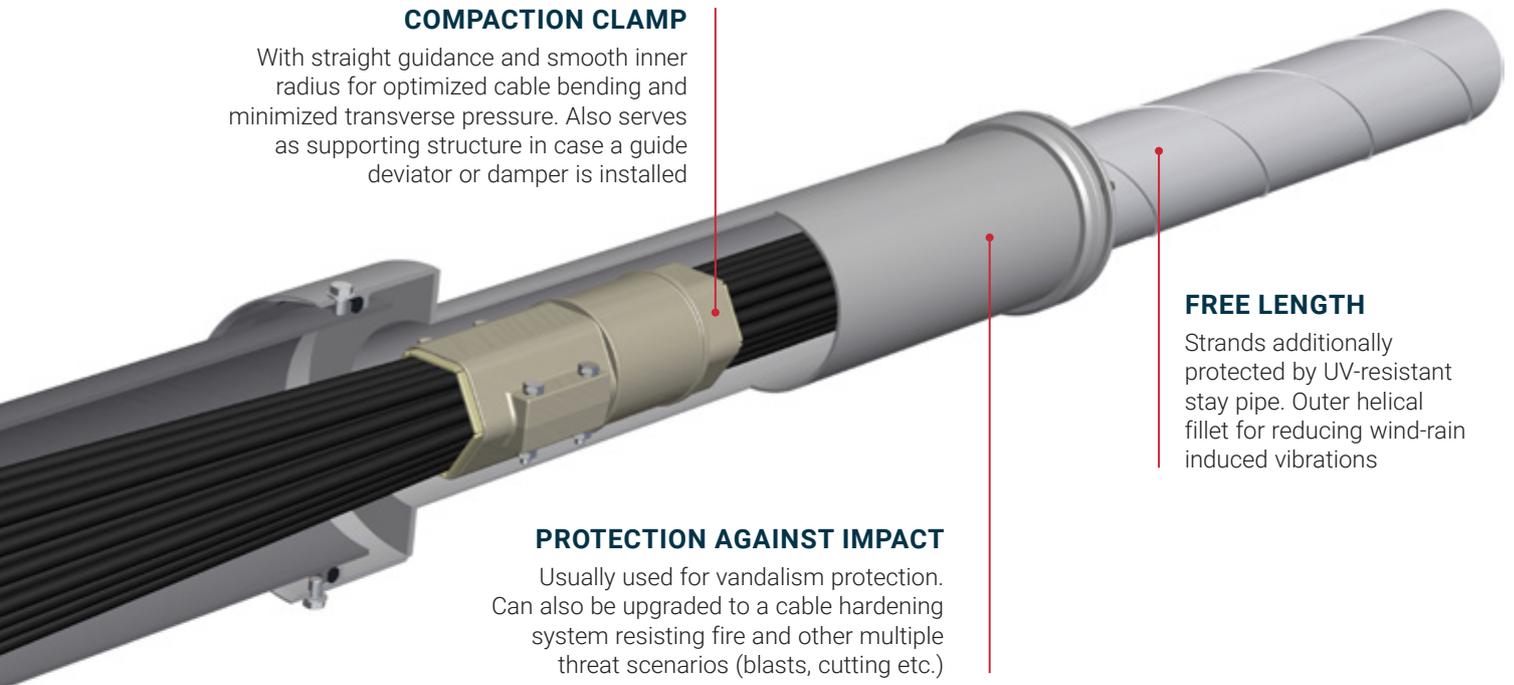

The system has proven its excellent performance and fulfills the requirements of *fib* Bulletin 30 as well as PTI & Setra requirements for fatigue and tensile strength:

- Multiple full size tests on cable sizes from 7 to 156 strands
- Tests on single strands under reversed cyclic flexural loading with 45% and 60% GUTS, 2 million load cycles with anchorages inclined by 3.0° and additional angular deviation between $\pm 10\text{mrad}$ and $\pm 35\text{mrad}$

- The system has been successfully tested in standard tests with a stress range of up to 200MPa at an upper stress limit of 45% GUTS and at 2 million load cycles with anchorages inclined by 0.6°. In addition, full size tests have been performed successfully with an upper load of up to 60% GUTS, up to 10 million load cycles and a stress range of up to 250MPa

The leak tightness of the anchorage area has been demonstrated for the complete system and even meets stringent fib and Setra requirements with:

- Up to 3m water head
- Several load cycles in the longitudinal and transverse direction
- Temperature cycling 20–70°C

COMPACTION CLAMP

With straight guidance and smooth inner radius for optimized cable bending and minimized transverse pressure. Also serves as supporting structure in case a guide deviator or damper is installed

FREE LENGTH

Strands additionally protected by UV-resistant stay pipe. Outer helical fillet for reducing wind-rain induced vibrations

PROTECTION AGAINST IMPACT

Usually used for vandalism protection. Can also be upgraded to a cable hardening system resisting fire and other multiple threat scenarios (blasts, cutting etc.)

DURABILITY AND HIGH-QUALITY CORROSION PROTECTION

Strands are guided into the anchorage by an elaborate system that ensures both leak tightness and smooth deviation:

- Compressible sealing plates ensure water and even vacuum tightness
- The correct function can be checked and even adjusted during inspection
- Bending stresses are minimized by a filter that arranges a straight-line entering into the wedge gripping area
- A cap including filler material for the protection of individual strands is placed in front
- Corrosion protection resists corrosivity class C5 in accordance with ISO 12944

The anchorages have been designed for threading the strands including their PE-sheathing through the anchorage:

- Dismantling of the strand's PE-sheathing is minimized to what is absolutely necessary.
- The factory applied corrosion protection of the strands continues directly up to the wedges.
- Significant reduction of the length of anchorage area where interstices are filled with corrosion protection compound. Both high durability and cost savings in terms of additional filling material are guaranteed.

Free length:

- The strands are protected by a multi-layer system of galvanized wires and are tightly sheathed by HDPE. A wax filling is used for the interstices in between.
- An outer stay pipe made of UV-resistant HDPE additionally protects the strands and minimizes rain-wind induced vibrations with an outer helical fillet that provides a low drag coefficient.

REPLACEABILITY OF STRANDS

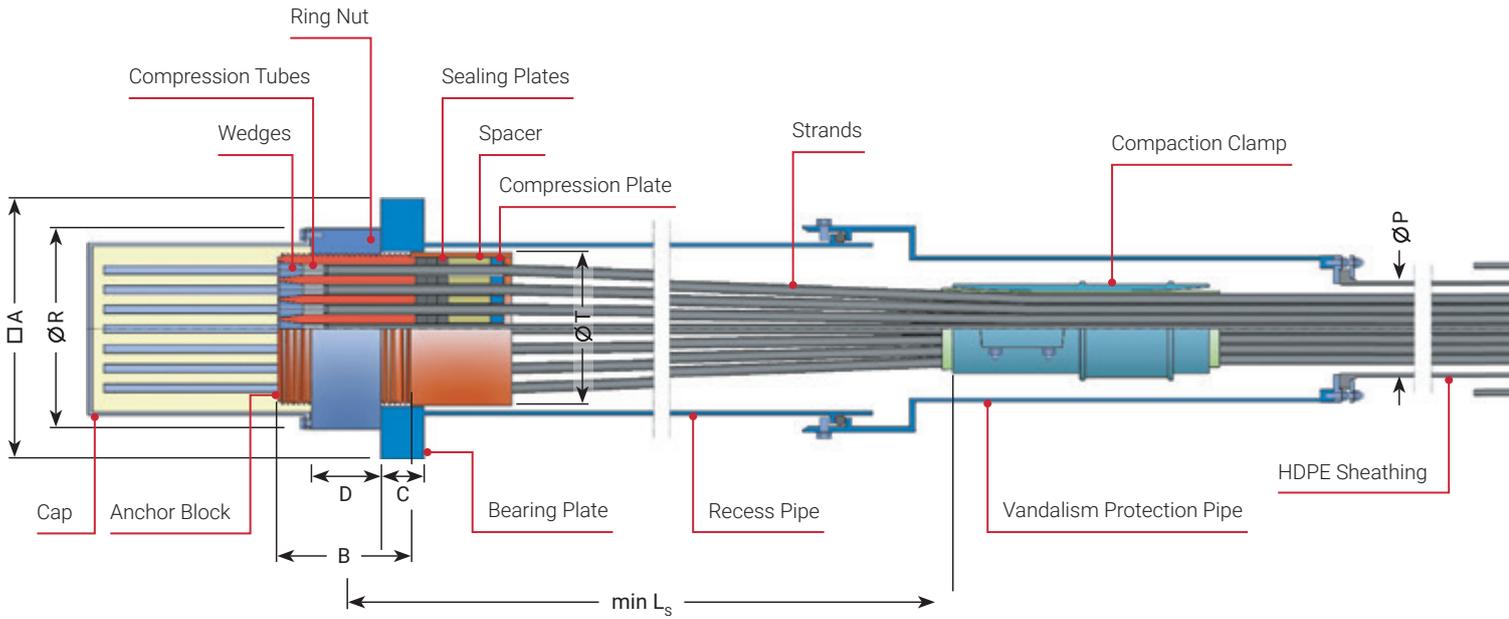

As the PE-coating is pulled directly through the anchorage, an exchange of strands is possible at any time during the service life of the bridge without the need for renewing or replacing any

- Strand exchange is performed directly at the anchorages
- There is no need for moving the cable's outer stay pipe for accessing the strand bundle either at the deck or outside the pylon – no disruptions to traffic.

FAST CONSTRUCTION CYCLES

- Lightweight equipment for strand installation and stressing operations is provided by DSI.
- A compaction clamp, installed after stressing on the strand bundle, keeps the strand in a compact hexagonal pattern.
- Non-protruding recess pipes at the pylon - no additional formwork adjustment is required.
- No exact dismantling of the strand's outer sheathing is necessary. In case of stressing actions that are additionally required, the strand sheathing is compressed by small tubes in front of the wedges while the strand is pulled through and elongated by the jack.
- The use of tower cranes or other lifting equipment can be limited to a minimum.

DYNA Grip® Stay Cable System - Optional Solutions

VANDALISM PROTECTION & GUIDE DEVIATOR

The DYNA Grip® Stay Cable System can be easily adjusted or upgraded if required:

- The length of the vandalism protection pipe can be adjusted to project specific requirements to achieve any requested height above the bridge deck level. It can be made of 2 long parts or customized for retrofitting purposes.
- On special request, guide deviators can be provided both at the deck and at the pylon to:
 - reduce cable bending at the anchorages
 - decrease cable vibrations
- DSI has patented (EP2729621 B1; US9009899 B2) an eccentric flange connection between the recess pipe and the housing for the guide deviator. The eccentric flange connection ensures that eccentricities caused by wrong installation angles of the recess pipe can be compensated.

CABLE HARDENING

DSI's cable hardening system has been developed to protect the stay cables effectively against multiple threat scenarios for all stay cable sizes.

- Any kind of mitigation level in terms of specific customized threat scenarios and the required strength of the protection system can be taken into consideration.
- Highly effective protection material can be easily adjusted to requirements and threats
- Numerical simulation and physical testing is carried out using expertise from Fraunhofer Institute for High Speed Dynamics (Ernst-Mach-Institute)
- Validation of different scenarios with specific threats following bridge security guidelines (e.g. AASHTO)
- Therefore, DSI's Cable Hardening system is designed according but not limited to the typical and notable threats as shown in table below
- Adaptable for bridge retrofitting applications using half-shell technology

Cable Hardening shows advantageous performance characteristics:

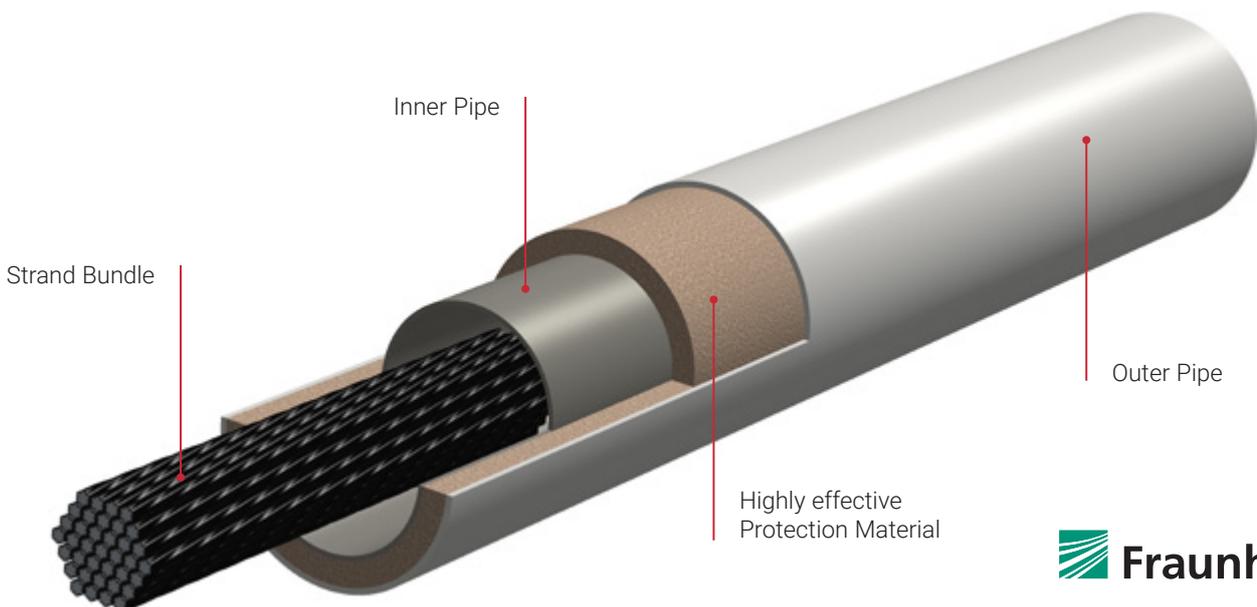

- Eases installation and is adjustable to different bridge construction methods
- Can be adjusted to any kind of bridge construction layout within anchorage and transition zones
- Incorporates adjacent functional cable units like dampers either internally or externally
- Allows easy inspection and maintenance of the protection system itself but also the stay cable system in general

CABLE HARDENING THREAT RESISTANCE

Threat	Type	Available
Fire	Hydrocarbon Fire	Yes
Explosive Device	HEIED	Yes
	VBIED	Yes
Non Explosive Device	Thermal Cutting	Yes
	Mechanical Cutting	Yes
	Exothermic Lance	Yes

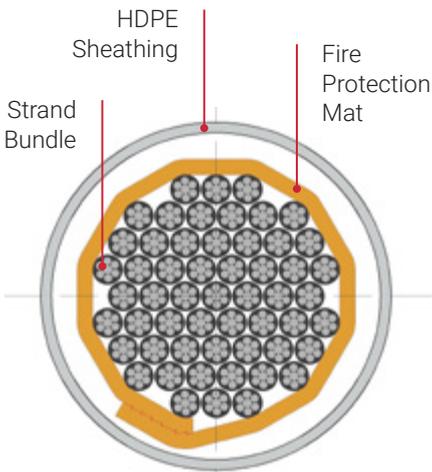

Exothermic Lance

FIRE PROTECTION

Lightning, a car accident or other external incidents may cause fire on a bridge. In that case, the main parts of the stay cable system need to be protected against damage.

FIRE PROTECTION MATS FOR THE FREE CABLE LENGTH

DSI's stay cable system fully complies with PTI requirements for fire resistance and has been verified using the load capacity test at 300°C.

Furthermore, special fire protection mats resist a 1,100°C hydrocarbon fire for at least 30 minutes without the strands heating up to above 300°C, thus fully complying with PTI requirements.

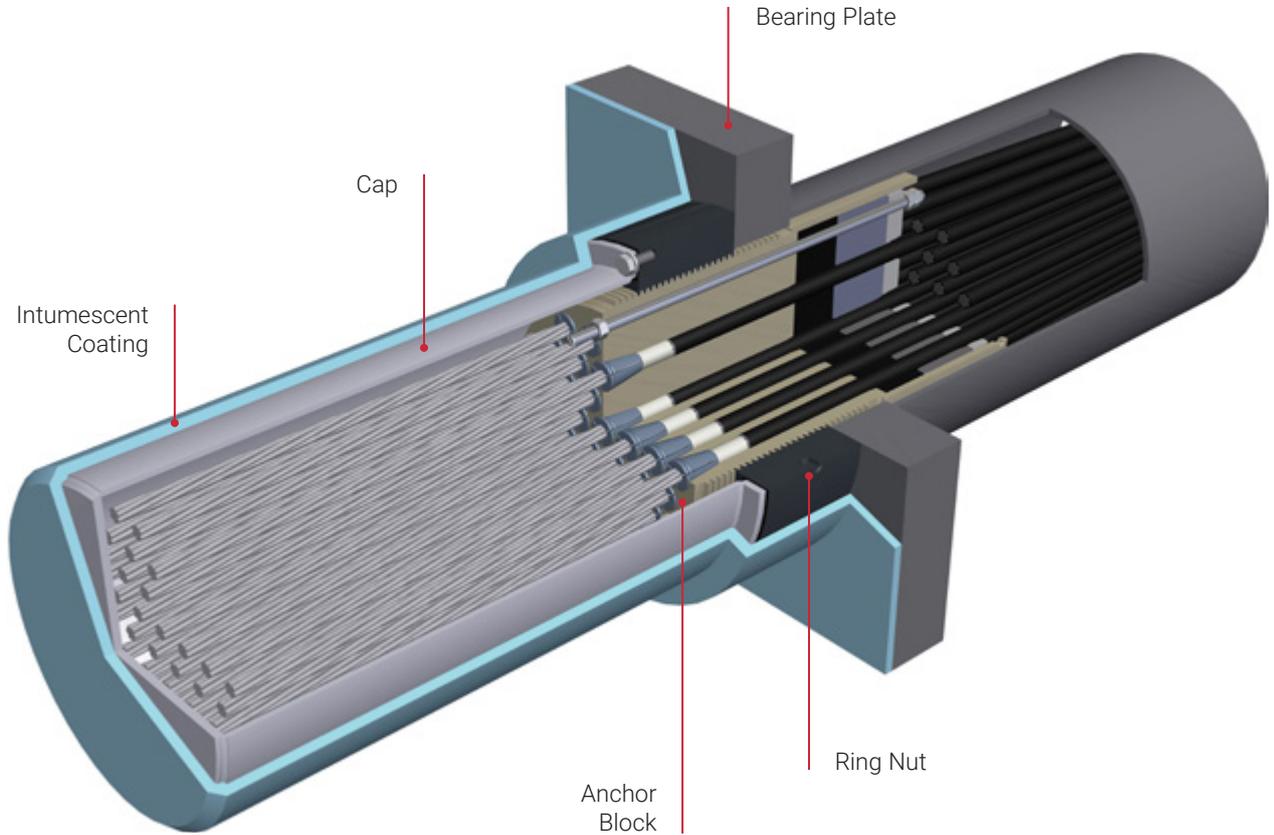

- Used for the free length of the stay cable
- Covered by standard HDPE sheathing
- Mats have a hydrophobic behavior to avoid water absorption
- Any other fire resistance period can be achieved easily by modifying the mat thickness
- Application in cable transition zone is possible

ANCHORAGE AREA

- Steel parts in the anchorage area can be coated with a special fire protection coat that is intumescent under heat impact and thus protects the steel parts
- Protection has been demonstrated during laboratory tests
- Fire protection coating fulfills the highest requirements according to standard ISO 12944, corrosivity class C5

ANCHORAGE PROTECTION SYSTEM

CABLE DE-ICING

Methods are available to reduce the risk of snow and ice accumulation falling from stay cables and endangering traffic running on the bridge's superstructure.

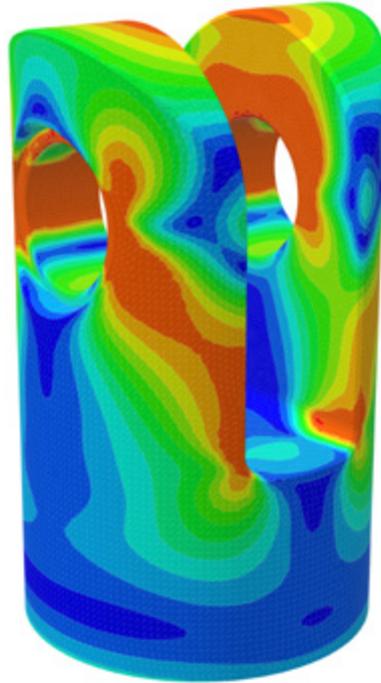

Patented measurements are designed, eliminating the risk of harming the cable structure. In order to comply with client specific needs in dependence of different climatic conditions,

DSI closely cooperates with globally recognized expertise and testing facilities.

CLEVIS ANCHORAGE

- Architectural requirements for the design of stay cable bridges are steadily increasing. Pylons often need to be as slim and elegant as possible.
- Solutions are needed in which the stay cables are connected to the structure outside of the pylon if the space inside the pylon is insufficient for common stay cable anchorages that are supported by bearing plates.
- DSI developed the DYNA Grip® Clevis Anchorage for strand cable types DG-P4 to DG-P61 as standard sizes with additional types on request, offering an economic alternative to conventional systems that have been used so far.
- The complete strand cable can be easily pre-assembled on the superstructure and is lifted into its final position afterwards.
- DSI offers special tools for the preassembly of the clevis as well as the mounting of the pin into the clevis hole.
- Restressing of individual strands as well as the replacement of the complete strand bundle is possible.
- This system also offers other DYNA Grip® System advantages.

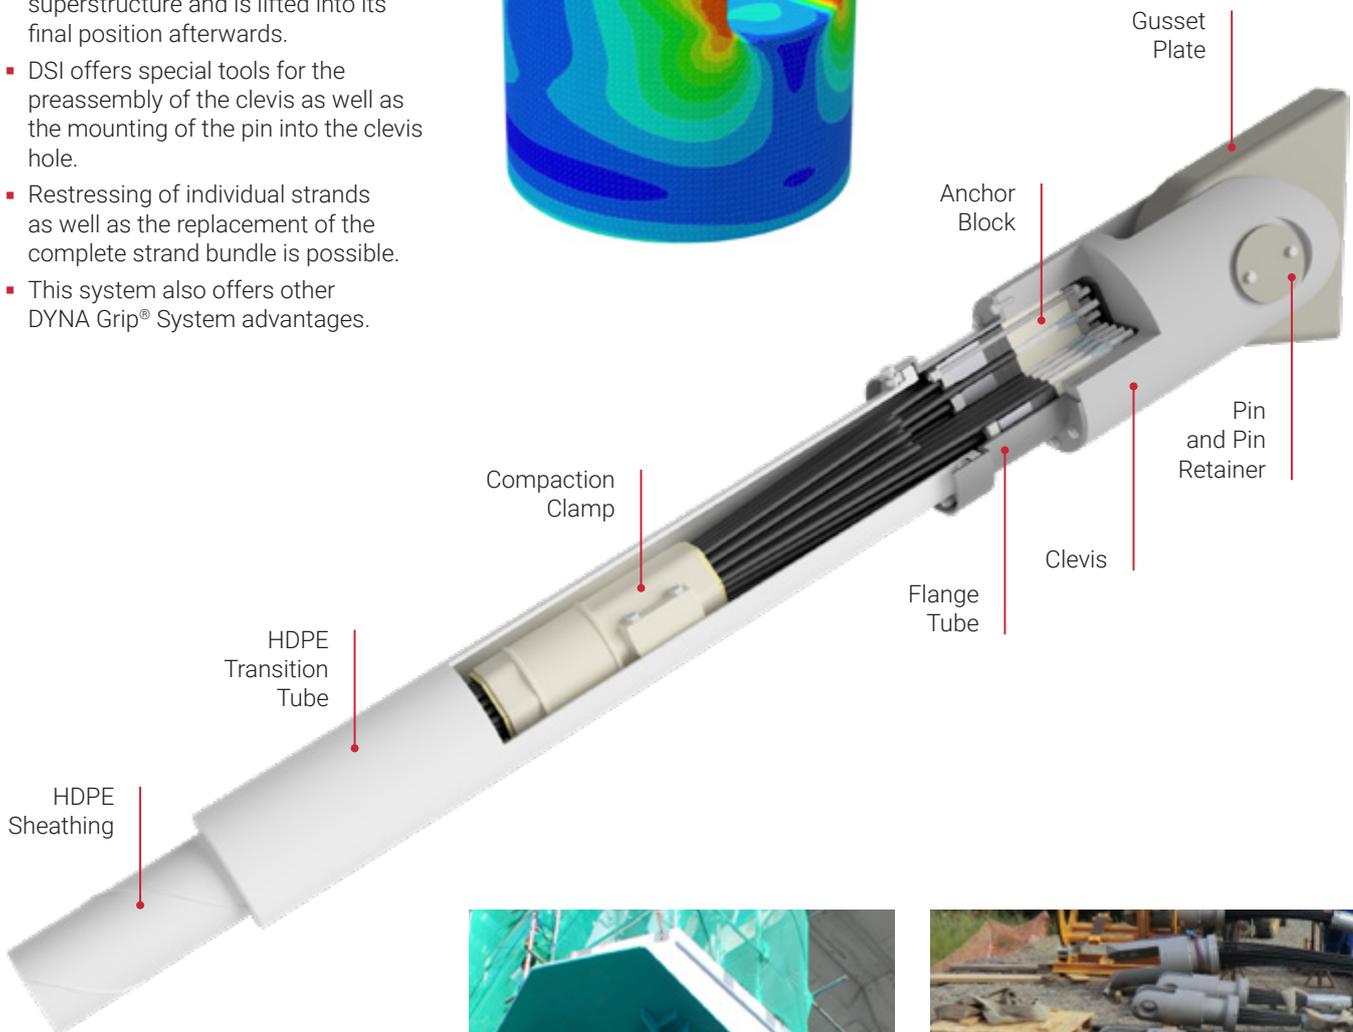

Fatigue tests were carried out at the Technical University of Munich in accordance with *fib* Bulletin 30 requirements.

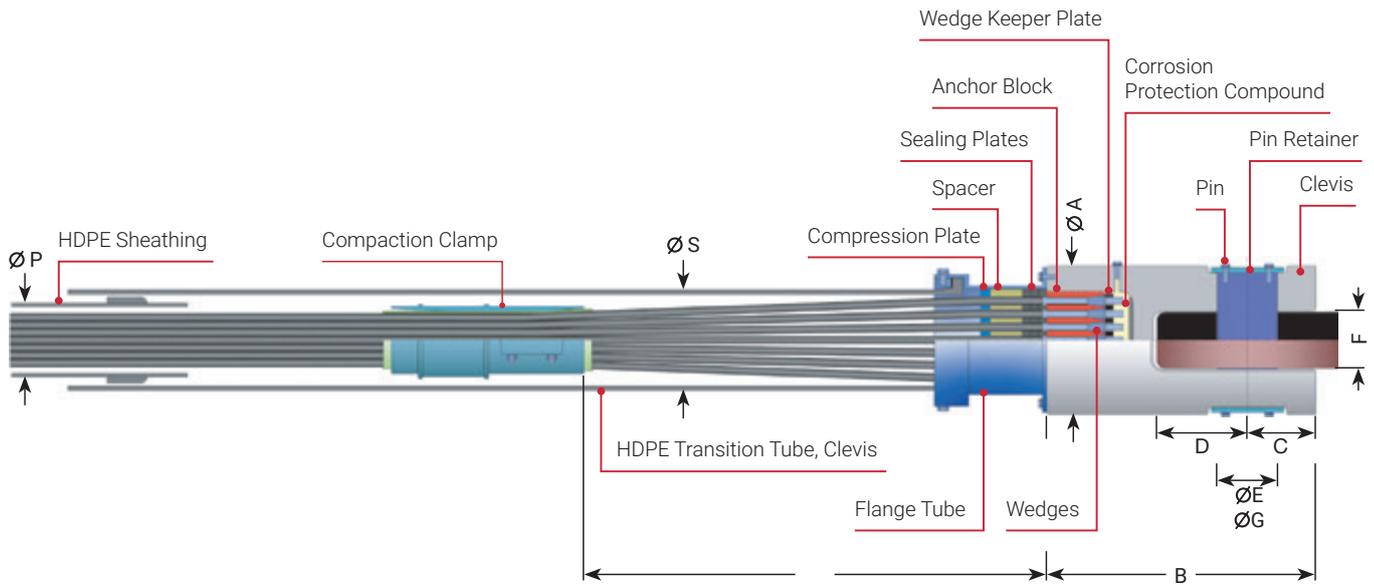

The tests respected an inclination of 0.6° – even towards the inflexible centerline – and an upper load of 0.45 GUTS. They were carried out with a stress range of 200N/mm² at 2 million load cycles.

These dynamic tests, as well as the subsequent static tensile tests, were performed with outstanding success.

The clevis anchorage is not only suitable for stay cable bridges, but can also be used for arch bridge hangers where available space in the arch is too small for aligning ordinarily fixed anchors.

DYNA[®] Link Anchor Box System

The DYNA[®] Link Anchor Box System is based on a conventional steel structure in which stay cables are anchored with standard DYNA Grip[®] anchorages. The DYNA[®] Link curved Anchor Box is economically designed using conventional steel construction standards to ensure capacity, serviceability and excellent fatigue characteristics. Differential forces are transferred to the concrete by shear studs in regular design, which are welded to the outer surface of the Anchor Box flanges.

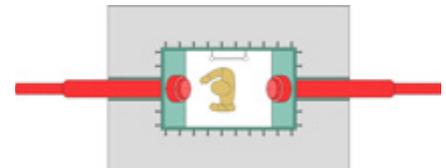

ADVANTAGES IN COMPARISON TO CONVENTIONAL PYLON SOLUTIONS

The DYNA[®] Link Anchor Box features many advantages in comparison to conventional pylon solutions in which cables are anchored inside the pylon section:

- When using DYNA[®] Link Anchor Boxes, pylon dimensions can be significantly reduced by eliminating anchorages inside the pylon. This allows slender and aesthetical pylon shapes.
- The pylon does not need to be hollow to allow access for installing, stressing and servicing the anchorages.
- Total cost and construction time of the pylon can be reduced.
- Easy and fast installation of box and stay cable with minimum manpower during cable installation.
- The horizontal load can be transferred directly through the DYNA[®] Link Anchor Box with reduced stresses within the concrete.

DYNA[®] Link Anchor Box

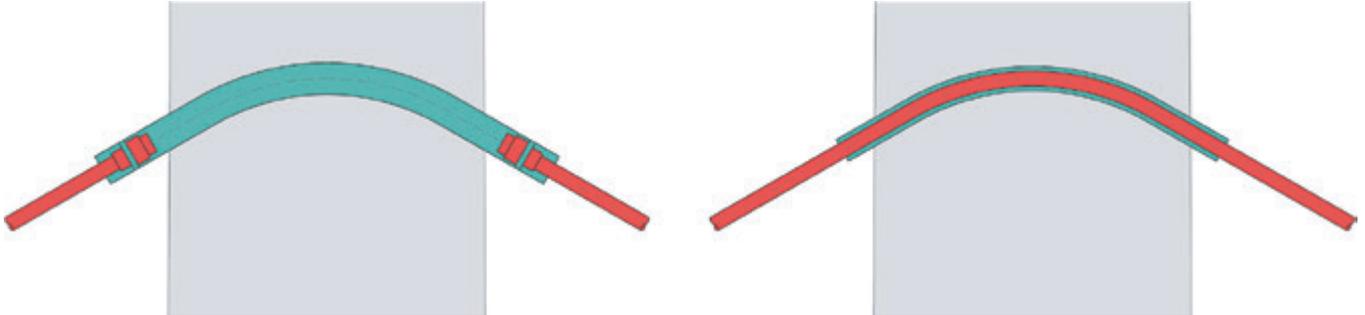

Accessible Steel Box

ADVANTAGES IN COMPARISON TO CONVENTIONAL SADDLE SOLUTIONS

The DYNA® Link Anchor Box features many advantages in comparison to conventional saddle solutions in which strands are guided through the pylon:

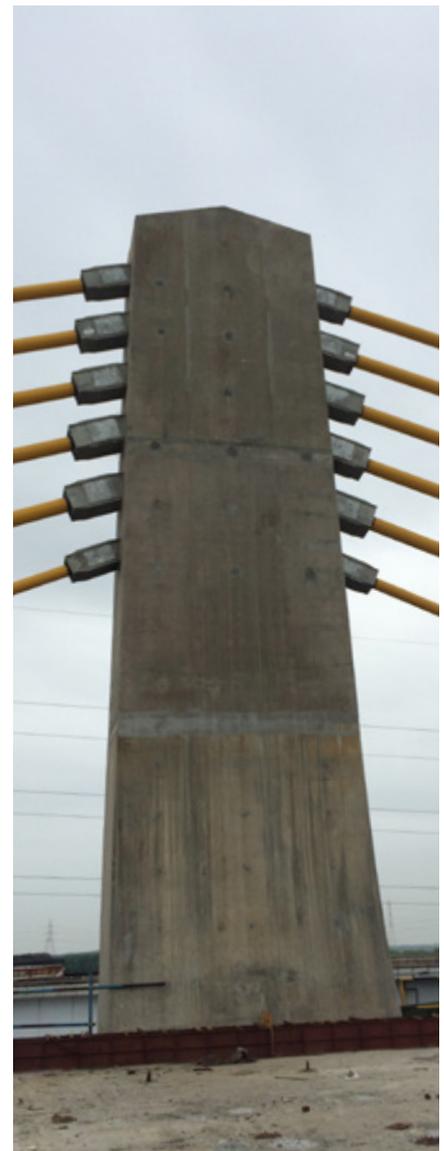

DYNA® Link

Conventional Saddle

Topic	Description	Conclusion
Bridge Design	<p>The use of conventional saddles results in equal strand numbers on both sides of the tower for each cable. This outcome might not be the most efficient or desirable from an economical and behavioral point of view. This is evident for end spans that have a considerably larger stiffness than adjacent main spans and particularly for cables anchored close to end supports.</p> <p>There is also uncertainty on what is the effective cable length to be used in the structural analysis. This uncertainty stems from the fact that a certain length of the curved strands inside the saddle will be subjected to varying axial strains. This effect may be significant for the shorter cables of Extradosed bridges.</p>	<p>With the DYNA® Link Anchor Box, the stay cable assembly is flexible. Different cable sizes can be used, and the effective cable length with a working point at the anchorage is clearly defined.</p>
Friction Factor and Slip Limit State	<p>Slip in conventional saddles is prevented by friction between the strands and the saddle. Current design recommendations (such as PTI recommendations and <i>fib</i> Bulletin 30) require that the friction factor be derived from tests on specimens representing the parameters of the actual saddles. These tests are conducted in the laboratory in dry and controlled conditions. Due to possible contamination or condensation, the conditions in an actual saddle on site may be quite different from the test conditions. This creates uncertainty as to the actual friction factor available to resist differential cable forces during the construction and service stages of the bridge.</p> <p>Slip of strands inside a saddle must be completely avoided. This is an additional limit state that must be investigated and verified by the bridge designer. This limit state is not related to the strength of the cable components, but depends on the friction between strand and saddle and the magnitude of the cable forces at both ends of the saddle. Additional load cases and combinations may need to be investigated using advanced analytical methods, to ensure that this limit state would not be violated.</p>	<p>By means of the DYNA® Link Anchor Box, the full cable force can be reliably taken at each side of the pylon. There is no limitation by a friction factor and there are no uncertainties of friction at different climatic conditions. Friction tests and additional slip limit stage investigations within the structural computation are not required.</p> <p>DYNA® Link Anchor Boxes can even be used in seismic regions where friction type saddles are not recommended.</p>
Bending and Transverse Stresses	<p>Due to the curvature of saddles, bending and transverse stresses are transferred to the strands. The bending stresses will reduce the axial strength of the strands. The transverse stresses may result in fretting effects between the strand wires or between the strands and the saddle that will result in reduced fatigue strength of the strands.</p>	<p>At the DYNA® Link Anchor Box, the strands are not deviated along the saddle. Therefore, the fatigue performance and durability is not compromised, and existing full size fatigue and leak tightness tests of DYNA Grip® stay cable tests can be used. Furthermore, there are no limits in the respective saddle radii.</p>

ADVANTAGES TO CONVENTIONAL SADDLE SOLUTIONS

Topic	Description	Conclusion
Bridge Construction	The use of cable saddles results in doubling the man power and equipment required for the installation and stressing of cables. In addition, saddles require the pace of cantilever construction on both sides of the tower to always be symmetrical before a cable may be installed. This results in increased construction costs and inefficient utilization of resources.	The DYNA® Link Anchor Box provides full flexibility for the construction cycle, as cables may be installed alternately so that the overall construction time can be significantly reduced.
Cable Inspection and Maintenance	Saddles do not allow the inspection of strands inside them. This may be critical because the strands are anchored by friction inside the saddle pipes and are subjected to multi-axial stresses and differential movements due to live and dynamic loads. These conditions may adversely impact the design life of the strands and their corrosion protection system; and this uncertainty may not be acceptable to bridge owners.	The durability of the DYNA® Link Anchor Box is not compromised, as there are no strands which are deviated. Window opening at the DYNA® Link Anchor Box allows easy access for inspection and maintenance. It is even possible to replace a complete strand bundle only on one side of the pylon.

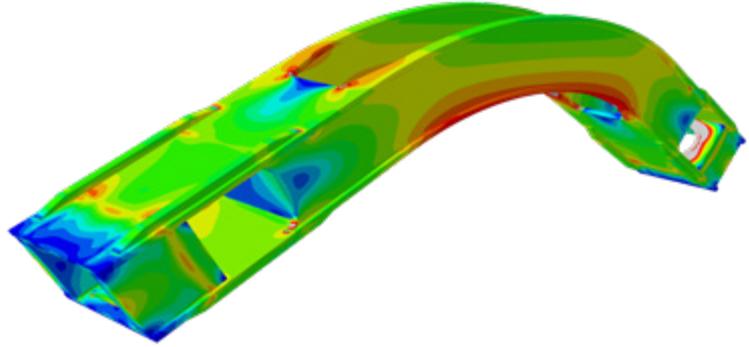

STAY CABLE INSTALLATION

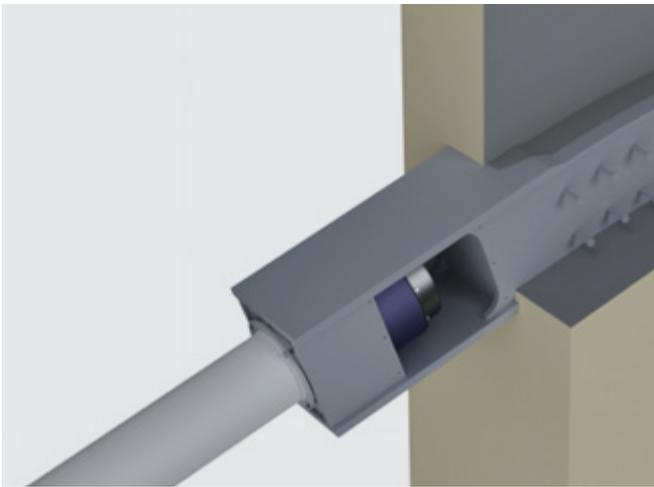

Depending on the pylon dimensions and cable layout, the DYNA® Link Anchor Box may either be provided with a lateral or a top access at the pylon interface for stay cable installation.

Standard solutions for both options have been designed for each cable type using Finite-Element Analysis software with the following design assumptions which are based on SETRA:

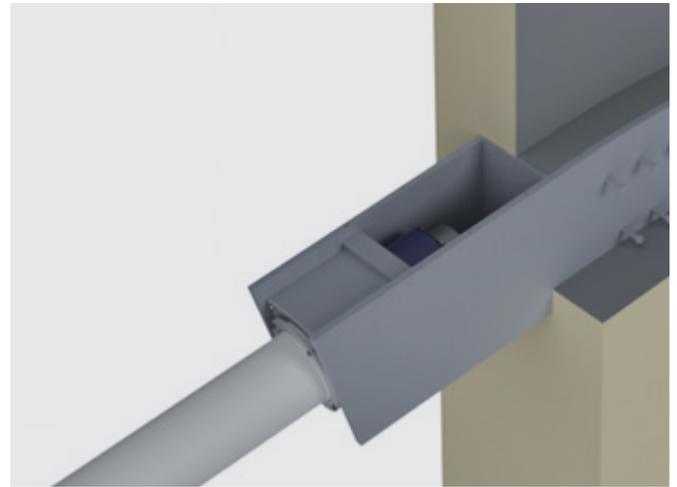

All standard solutions can be adapted easily to any project specific demand, and thus, the actual pylon dimension, cable angles as well as design loads will be taken into account.

Von Mises stresses of a DYNA® Link Anchor Box with lateral access

Lateral Installation opening for DYNA Grip® Stay Cable Anchorage

Open top Installation opening for DYNA Grip® Stay Cable Anchorage

Type	Load Level	Deviation
ULS DESIGN LOAD	90 % GUTS	+ 25 mrad deviation angle
SLS DESIGN LOAD	45 % resp. 60 % GUTS (stay cable resp. extradosed)	+ 25 mrad deviation angle
FLS DESIGN LOAD	200 MPa at 45 % GUTS resp. 140 MPa at 60% GUTS	+ 10 mrad deviation

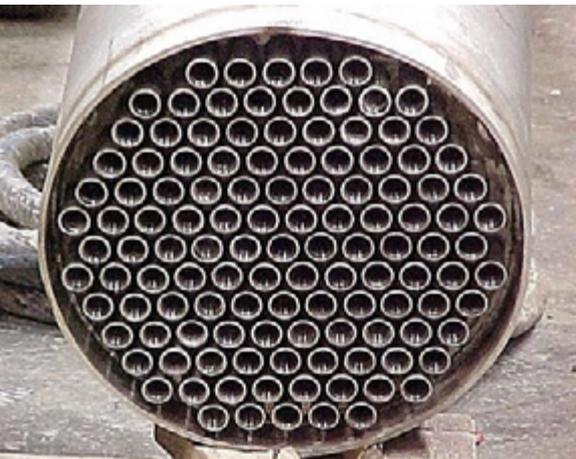

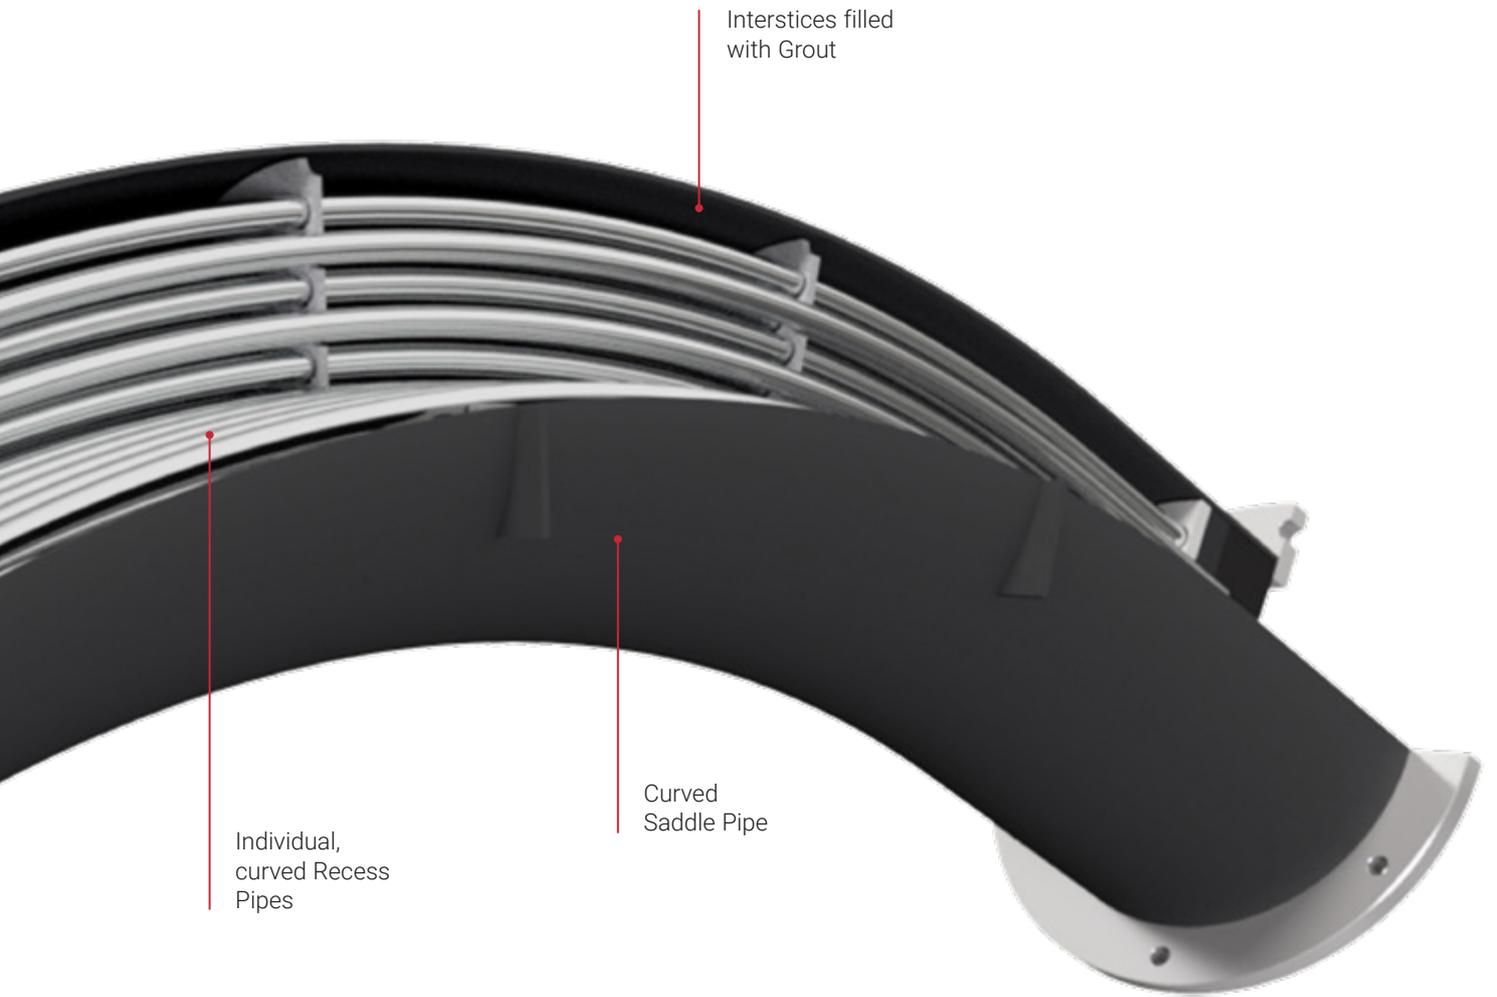

Saddle Solution

SADDLE WITH INDIVIDUAL TUBES

If strands need to be guided through the pylon structure and a transfer of forces by friction is required, DYWIDAG offers a saddle in which the strands are guided from one side of the pylon to the other:

- Strands are placed into a multitude of individual, curved recess tubes. The interstices between the saddle tube and the recess tubes are grouted
- The saddle itself is embedded into concrete
- Individual strands can be replaced
- Differential forces are transferred by friction
- Application of Epoxy coated strands and consequently:
- no peeling of strands' sheathing within the saddle necessary
- no pressure; the coating is therefore not in danger of being harmed, which can occur when using PE-sheathed strand

Fully Grouted Solutions

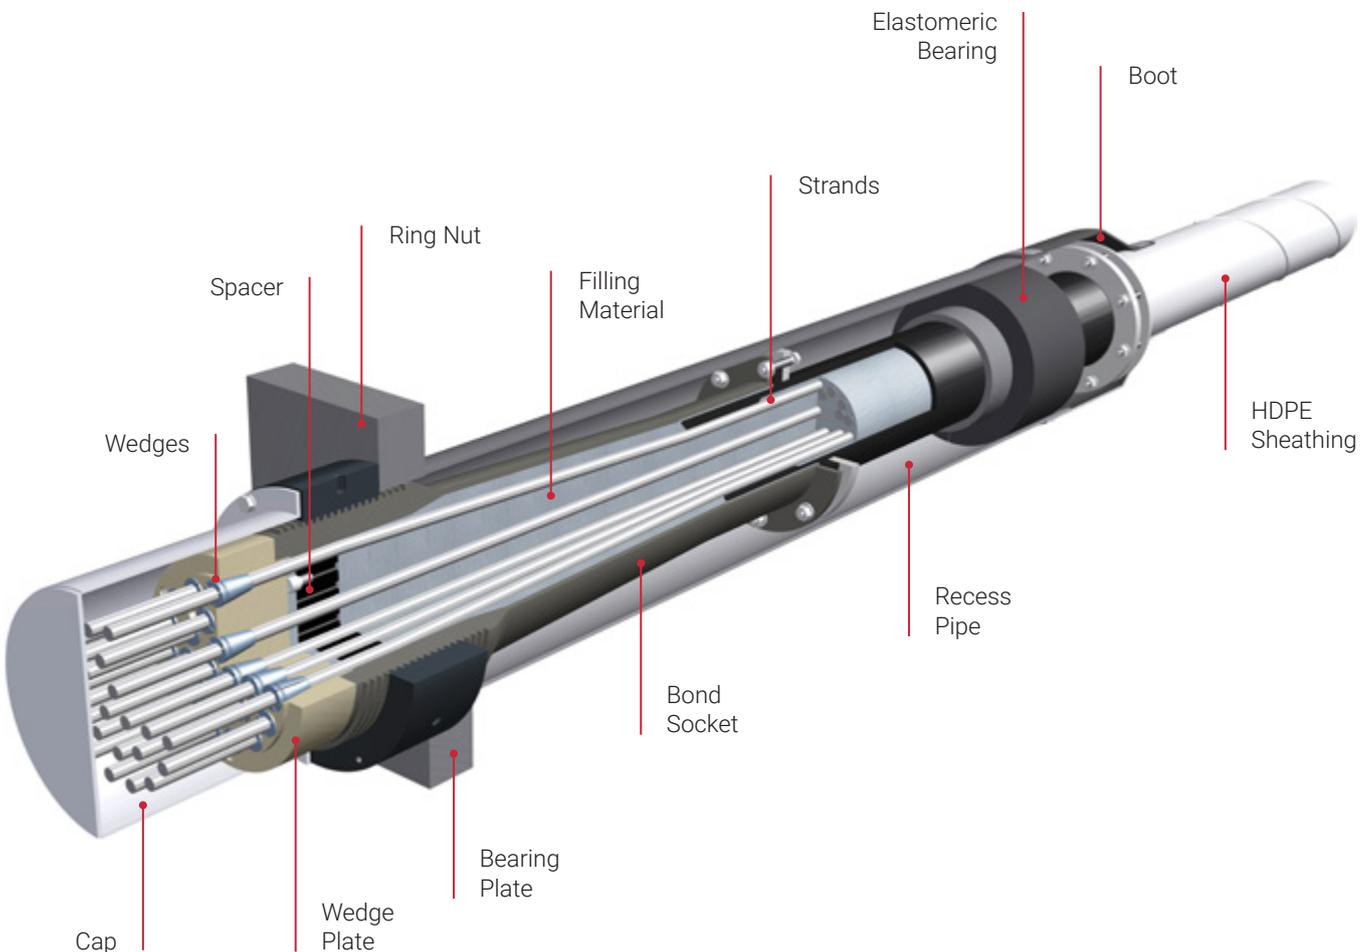

DYNA BOND® ANCHORAGE

The DYNA Bond® Anchorage consists of a conical steel pipe (bond socket) supporting a wedge plate in which the strands are anchored with high-fatigue 3-part wedges. A ring nut is fitted on the threaded end of the bond socket and distributes the cable force through a bearing plate into the structure.

- During the construction period – prior to grouting the bond socket – all the applied loads are supported directly by the wedges.
- At the final state of construction, all additional loads (live loads, vibrations and earthquakes) are partly resisted by both wedges and grouted bond socket.
- DYNA Bond® Anchorages have an excellent fatigue resistance because the bond action in the bond socket substantially reduces the magnitude of the dynamic loads reaching the wedge anchorage. Fatigue tests have proven a stress range of up to 240N/mm² at an upper load of 45% GUTS and 2 million load cycles.

ADDITIONAL ADVANTAGES

- Minimized bending effects at the anchorage by placing an elastomeric bearing inside the recess tube
- Reliable corrosion protection for the sensitive anchorage area, as all voids in the anchorage zone are filled with a stable and robust filler
- Enhanced fire resistance and protection against vandalism, impact loads and blast effects
- Easy fixation of external dampers directly on the grouted stay pipe
- A special patent protected sealing provision allows to grout the anchorage area only so that the free length remains without grout

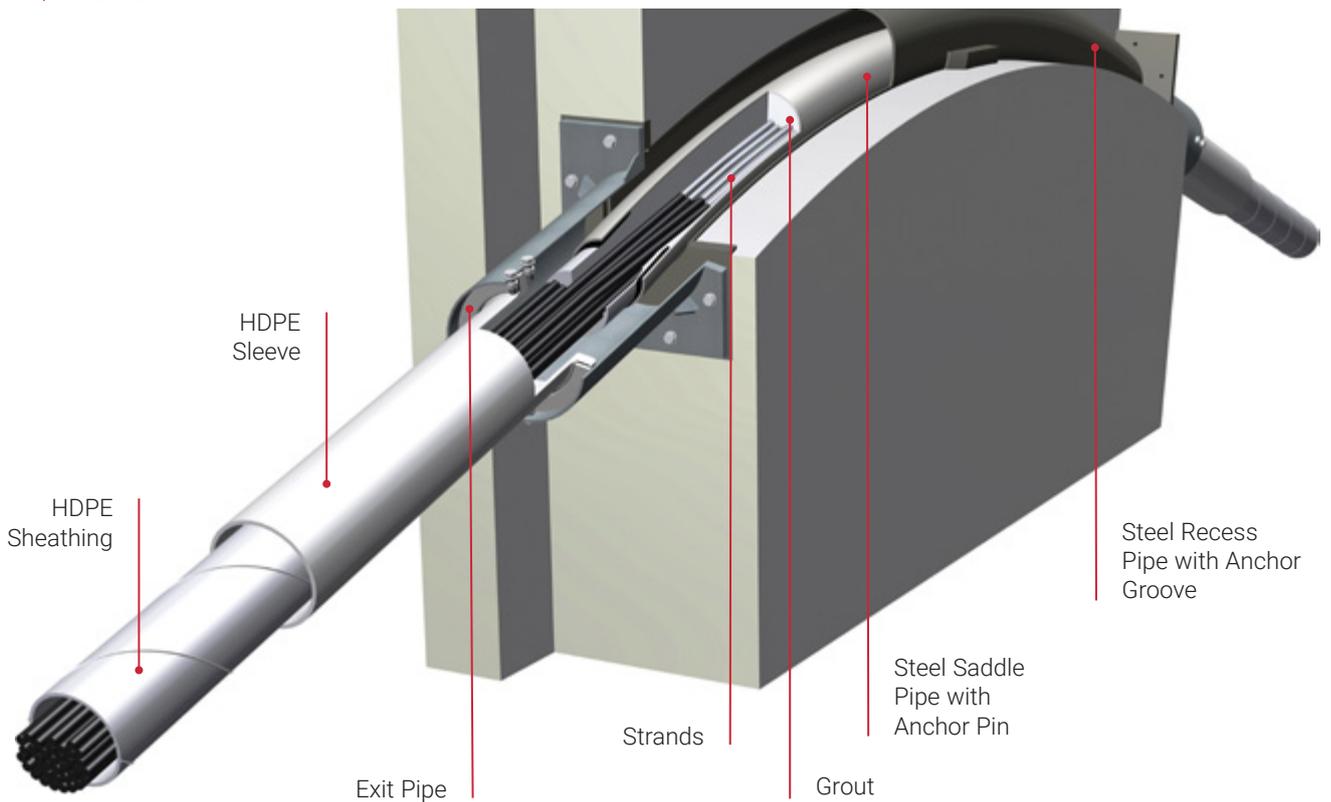

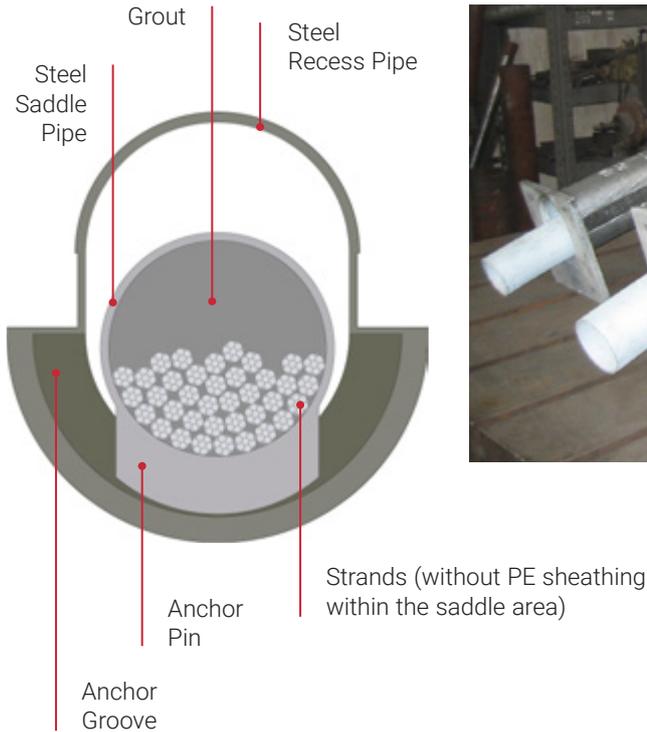

SADDLE WITH ANCHOR GROOVE AND PIN

The saddle transfers differential forces via a shear nose with pin into the pylon concrete construction.

- Strands (without PE coating inside the saddle) are guided in a curved tube and injected in the deviation area using special grout

- The strand bundle including saddle pipe can be exchanged if necessary
- An inner, curved saddle pipe is guided through an outer recess pipe that is embedded into the concrete

- Differential forces in the stays at both sides of the saddle are reliably transferred via a shear nose (anchor groove – pin construction)

Strand and Wedge

DYWIDAG Stay Cables use strands that meet the requirements of *fib* and *PTI-Recommendations* for stay cables, *ASTM*, *BS* as well as other national or international standards.

Generally, the following types of strands are used:

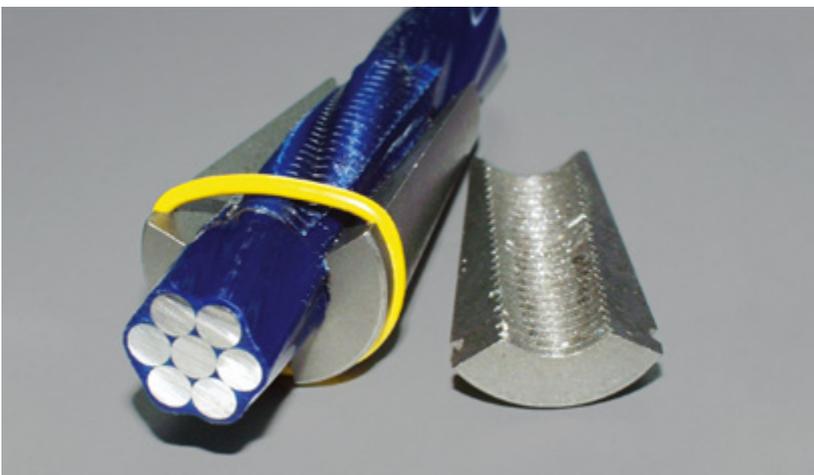

- 7 cold-drawn galvanized wires
 - PE-sheathed with minimum thickness of > 1.5mm in accordance with *fib* Bulletin 30
 - Low relaxation strand
- Wax as a void filler for the interstices between wires and PE sheathing
 - Diameters up to 0.62" and steel grades up to 1,860N/mm²
 - Strands are anchored with specially treated 3-part wedges that are characterized by high fatigue resistance.

EPOXY COATED STRANDS

- Epoxy coated strand is manufactured in compliance with ISO 14655:1999 or ASTM A882. The 3-part wedges are specially designed for epoxy coated strands. The teeth penetrate through the coating so that they grip into the wires of the strand.
- Fatigue tests conducted on single-strand tendons have proven a dynamic stress range of up to 260N/mm² (upper stress 0.45 GUTS at 2 million load cycles).
- Cold-drawn 7-wire strand is coated with epoxy resin in the shop
- Interstices between the 7 wires are completely filled with epoxy resin, thus providing excellent and robust long-time corrosion protection
- Epoxy material reduces fretting action between the individual wires and cushions adjacent strands in deviation areas. It avoids damages within the sensitive wedge gripping area and retains its properties as corrosion protection barrier
- The excellent bond of the epoxy with the steel wires and the ductile behavior of the epoxy material avoids damages within the sensitive wedge gripping area and retains its properties as a corrosion protection barrier
- An additional PE sheathing on top of the epoxy coating is possible, protecting strands from damage during handling and on-site installation

Wedge for Galvanized Strand

Wedge for Epoxy Strands

Epoxy Coated Strand

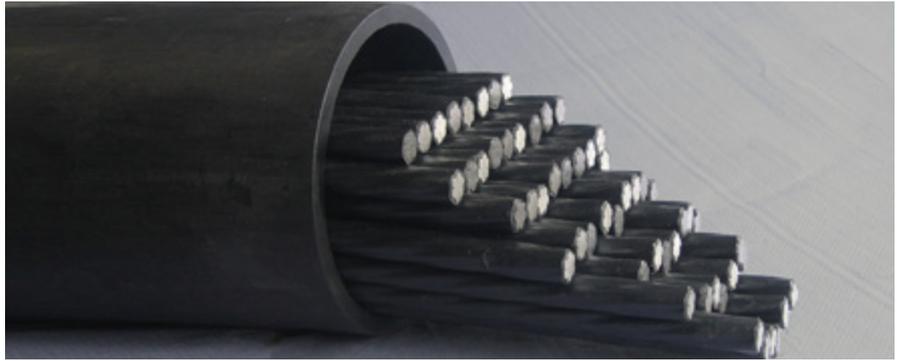

OUTER STAY PIPE

STANDARD PIPE

- HDPE pipes serve as protection against environmental influences and are typically used as outer covers of DYWIDAG Stay Cables. Main characteristics:
- Wind load reduction at the cable
- Outer helix with demonstrated efficiency against rain-wind induced cable vibrations
- Co-extruded or fully colored pipes
- Wide range of colors
- The excellent UV-resistance has been proven in accelerated aging tests
- Steel or stainless steel pipes are available on special request

SLIM DUCT

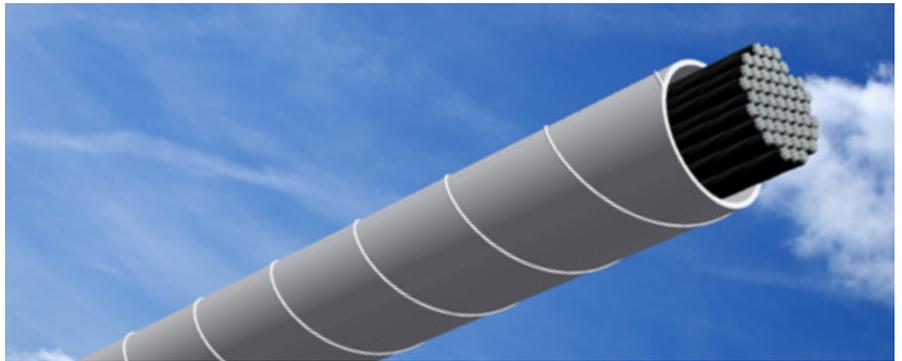

- For long span bridges, lateral wind loading at the cables needs to be taken into account for pylon design. To reduce the wind load, DSI offers slim sheathing with reduced pipe diameters.

Standard Duct

Slim Duct

HDPE Sheathing with Helix

Stainless Steel Duct

Cable Damping

Slender supporting structures and long cable lengths make stay cables susceptible to vibrations. Big vibration amplitudes may result in damages to the cable due to bending and fatigue loads. This decreases a cable's durability and may even endanger structural safety.

Depending on the respective cable parameters, each cable is more or less prone to vibration. Longer cables are more likely to vibrate than short ones. Nevertheless, cables with lengths above 200m have been installed without additional dampers without any vibration problems. On the other hand, even very short cables sometimes need dampers.

By experience, DSI recommends to increase a cable's inherent damping by using additional damping devices for cable lengths above 80m. Cables start vibrating when they are excited. Please find following some excitation causes and methods for mitigating their effects.

EXCITATION CAUSES

BUFFETING

- Wind causes drag, lift and moment forces on cables that result in cable vibrations. Depending on the boundary conditions, inherent damping of a stay cable without additional damping might not be high enough to decrease these vibrations to an acceptable amplitude.

VORTEX-SHEDDING

- Uniform wind flow causes turbulent vortices to detach, alternating from a cable's top and bottom side, so that vibrations are caused. The amplitudes are usually small compared to the cable diameter. However, resonance of the vortex shedding frequency and cable eigenfrequencies can result in larger amplitudes.

GALLOPING

- Galloping affects rectangular shapes or round shapes with asymmetry. If the wind speed is above a critical value, vortices detach from the edges and create similar effects as vortex shedding. However, contrary to vortex shedding, galloping results in high amplitude vibrations.

WAKE GALLOPING

- Wake Galloping occurs at cables that are closely spaced in wind direction. Vortices behind one cable excite the cable that is next to it and lead to vibrations.

ICED GALLOPING

- Ice that sticks to a round cable can alter its cross section in such a way that galloping occurs above a critical wind speed.

RAIN-WIND INDUCED VIBRATIONS

- During specific combinations of rain intensity, wind speed, wind direction and cable inclination, water rivulets arrange at the cable's top and bottom surface. Due to wind, they move a few degrees around the cable circumference and induce vibrations into the cable. This happens at relatively low wind speeds.

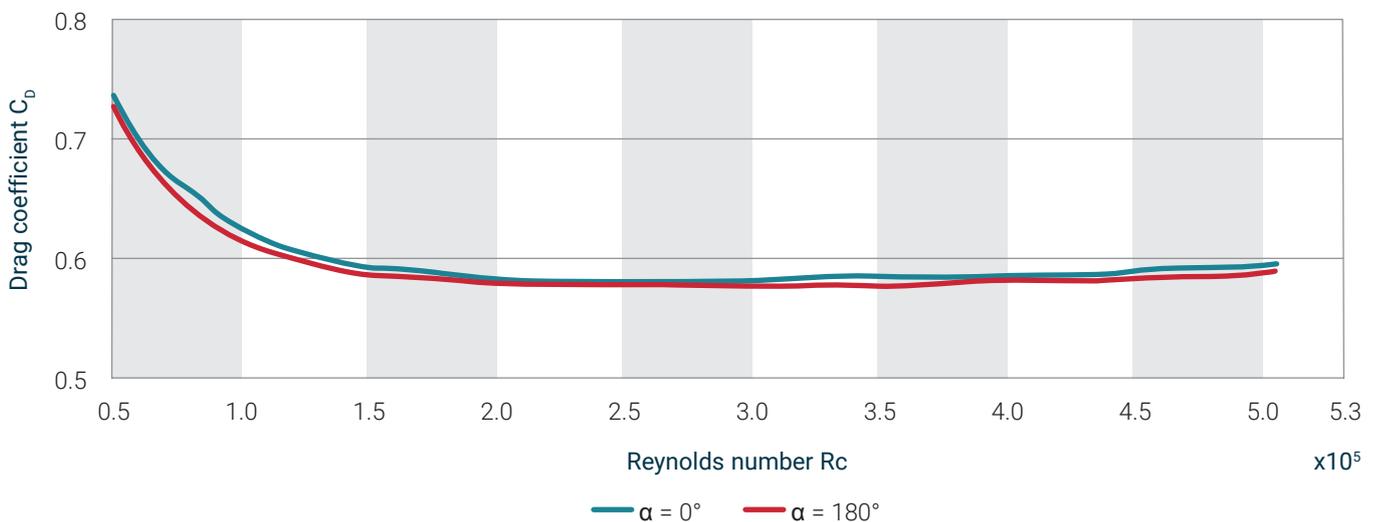

PARAMETRIC EXCITATION

- Parametric excitation is caused if the excitation acts on other parts of the structure (such as the pylon), and if this vibration is transferred into the cables.
- DSI not only supplies the appropriate damping devices but also supports bridge designers and owners in choosing a damping concept that is customized to their specific project needs.

OUTER HELICAL FILLET

- To mitigate rain-wind induced vibrations, a double helical fillet is applied on the surface of outer stay pipes
- Different diameters have been tested in climatic wind tunnel tests
- Demonstrated drag coefficient of $C_D = 0.6$ for large cable diameters

DRAG COEFFICIENT FOR STAY PIPE

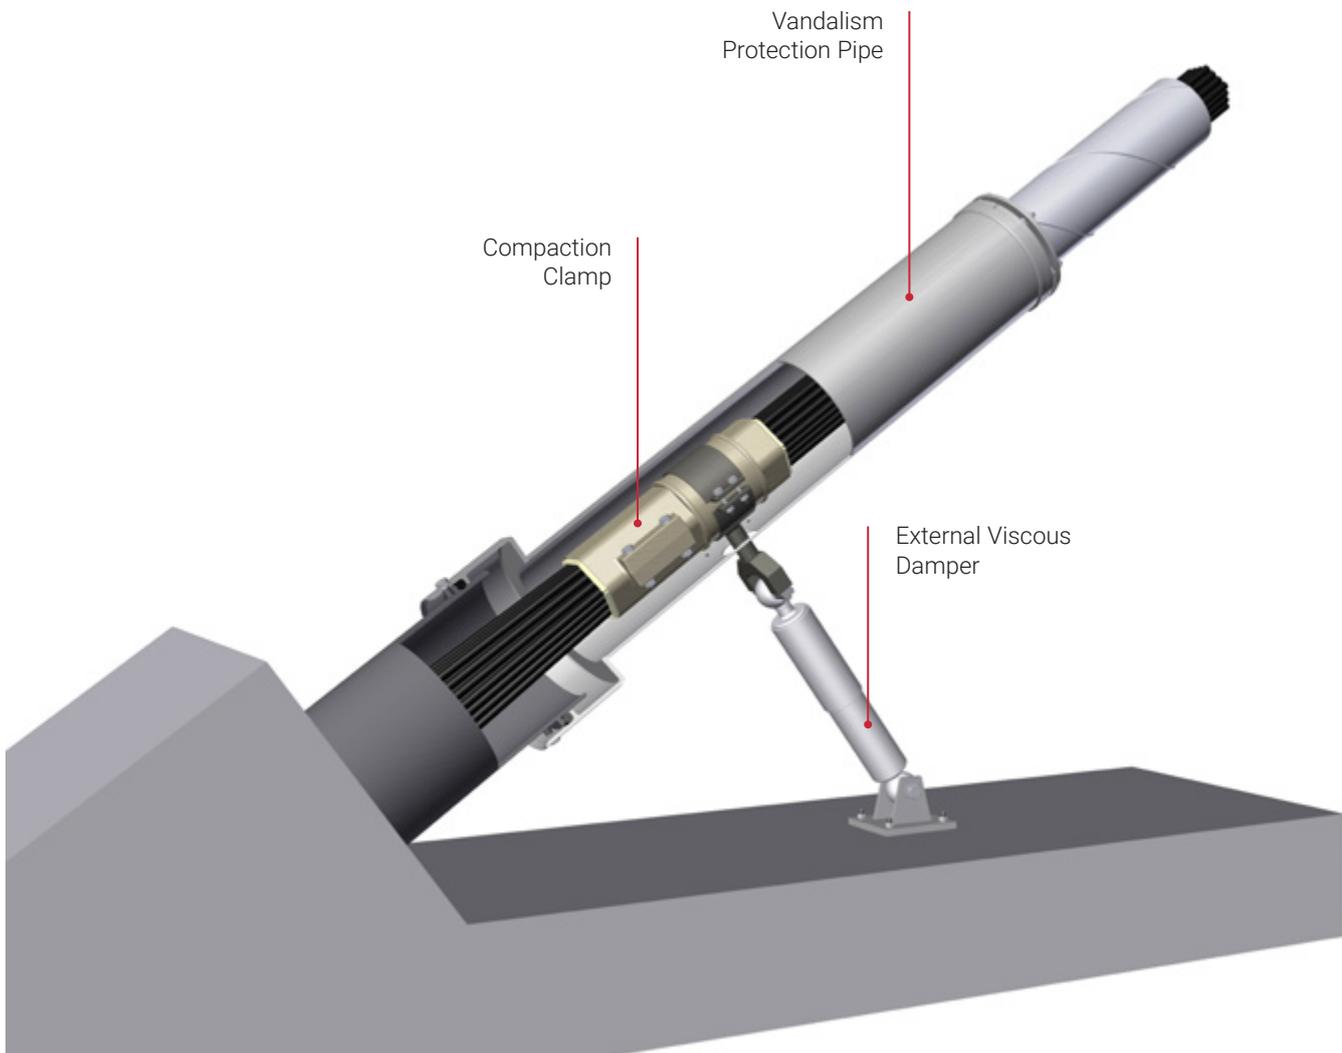

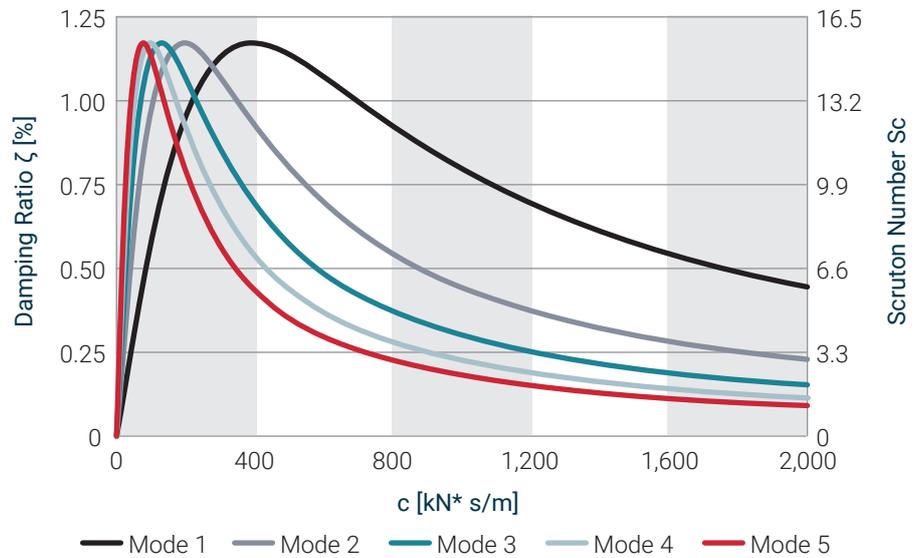

DAMPER DESIGN

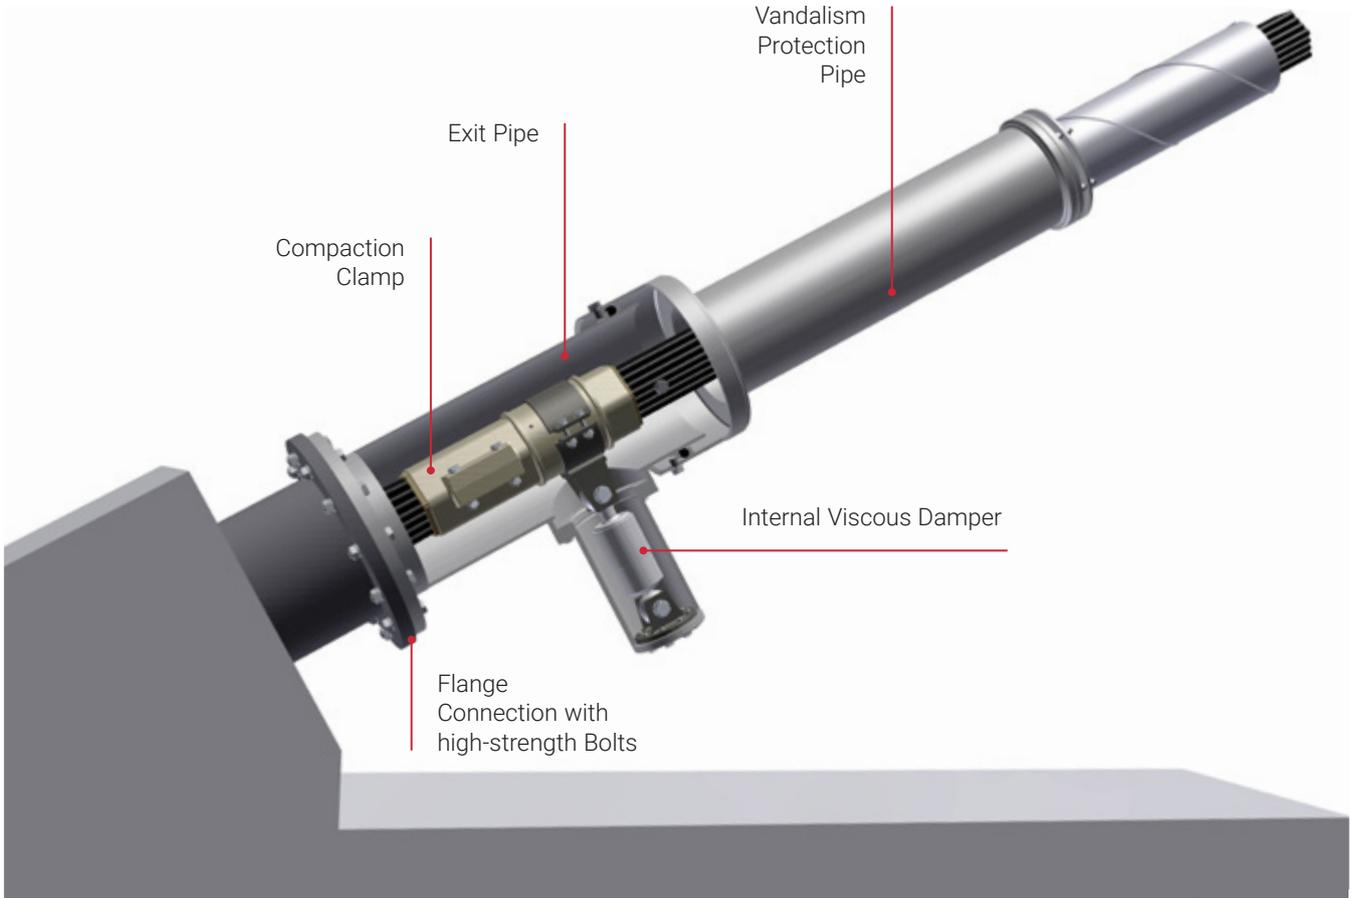

- Sufficient damping prevents cables from vibrating. DSI recommends damping values of at least 3–4% logarithmic decrement δ to be reached for the first two to three vibration modes depending on each cable's boundary conditions and on project specific requirements. These damping values can usually not be achieved by inherent cable damping so that additional damping is required.
- External viscous dampers provide very effective supplementary damping.
- Special software developed for DSI

EXTERNAL VISCOUS DAMPER

- Efficient dampers can be computed for each cable taking into account several vibration modes
- In plane, the damper is sufficient to also suppress out of plane vibrations
- Slender and aesthetic design; available in several colors

CORRELATION OF ACHIEVABLE DAMPING COEFFICIENT, DAMPING RATIO AND SCRUTON NUMBER

INTERNAL VISCOUS DAMPER

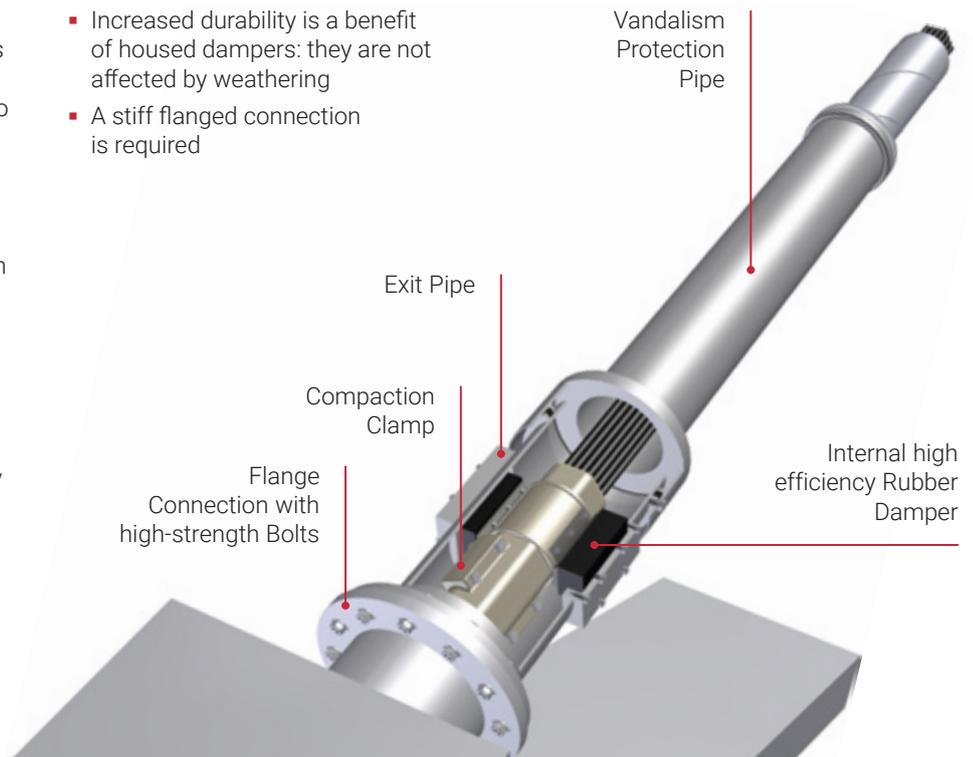

In addition to external viscous dampers, DSI also offers internal viscous dampers that are attached to the exit pipe.

- Damping forces are transmitted from the damper through its steel housing and exit pipe into the recess pipe, from where they are transferred into the superstructure
- Housed dampers are advantageous due to their avoiding additional support structures for connection to the bridge deck
- Since DSI housed dampers do not require a connection point on deck, they can be used at virtually any cable position
- Increased durability is a benefit of housed dampers: they are not affected by weathering
- A stiff flanged connection is required

INTERNAL RUBBER DAMPER

Especially used for short and medium cable lengths

- Internal rubber dampers are placed inside the exit pipe parallel to the cable axis
- Their elastomeric high efficiency material dissipates vibration energy while deforming when subject to shear stress

Full Size Testing

DYWIDAG Stay Cables have been successfully tested in numerous static and fatigue tests in compliance with *fib*, SETRA and PTI recommendations. Tests have been conducted in collaboration with renowned Universities such as CTL, TU Munich, TU Vienna, MPA Braunschweig or DTU Copenhagen.

STANDARD FATIGUE AND TENSILE TESTING

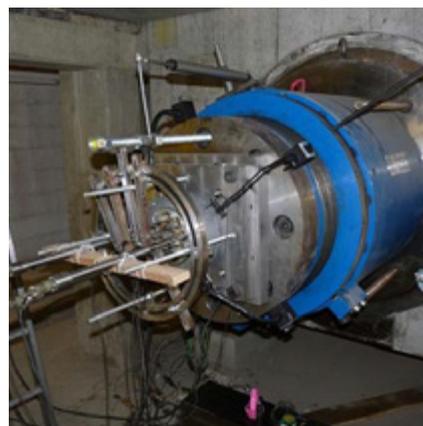

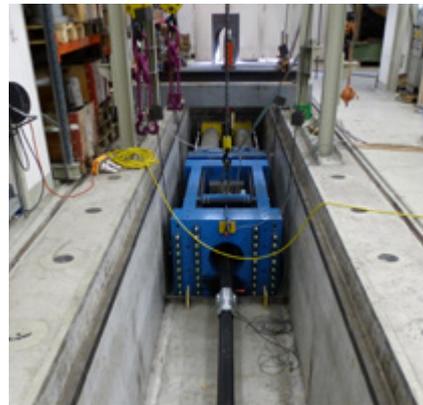

- Applying 2 million load cycles
- Stress range of 200N/mm²
- Upper load level of 45% GUTS
- Inclined anchorages of 10mrad

DYWIDAG Stay Cable testing has also been successfully conducted in additional full size tests with increased requirements in terms of upper load and additional angular deviation of the cable system.

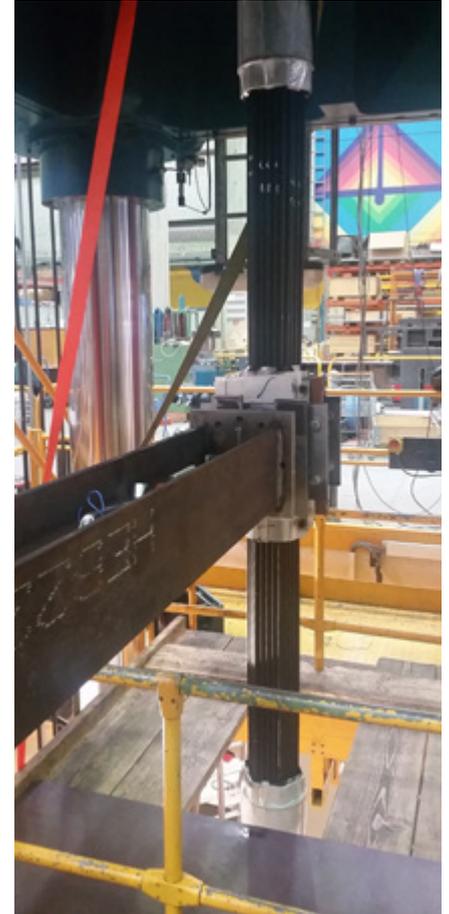

FATIGUE AND TENSILE TESTING WITH HIGHER LOAD LEVEL AND ADDITIONAL TRANSVERSE DEFLECTION

- Application of 2 million load cycles
- Stress range of 100N/mm²
- Upper load level of 60% GUTS
- Anchorages inclined by 10mrad
- Deviation of $\pm 25mrad$ in transversal direction

FATIGUE AND TENSILE TESTING WITH ADDITIONAL TRANSVERSE DEFLECTION (SETRA)

- Applying 2 million load cycles
- Stress range of 200N/mm²,
- Upper load level of 45% GUTS
- Transverse deflection resulting in cyclic angular deviation from 0 to 10mrad

INCREASED LOAD CYCLE TESTING – 10 MILLION CYCLES

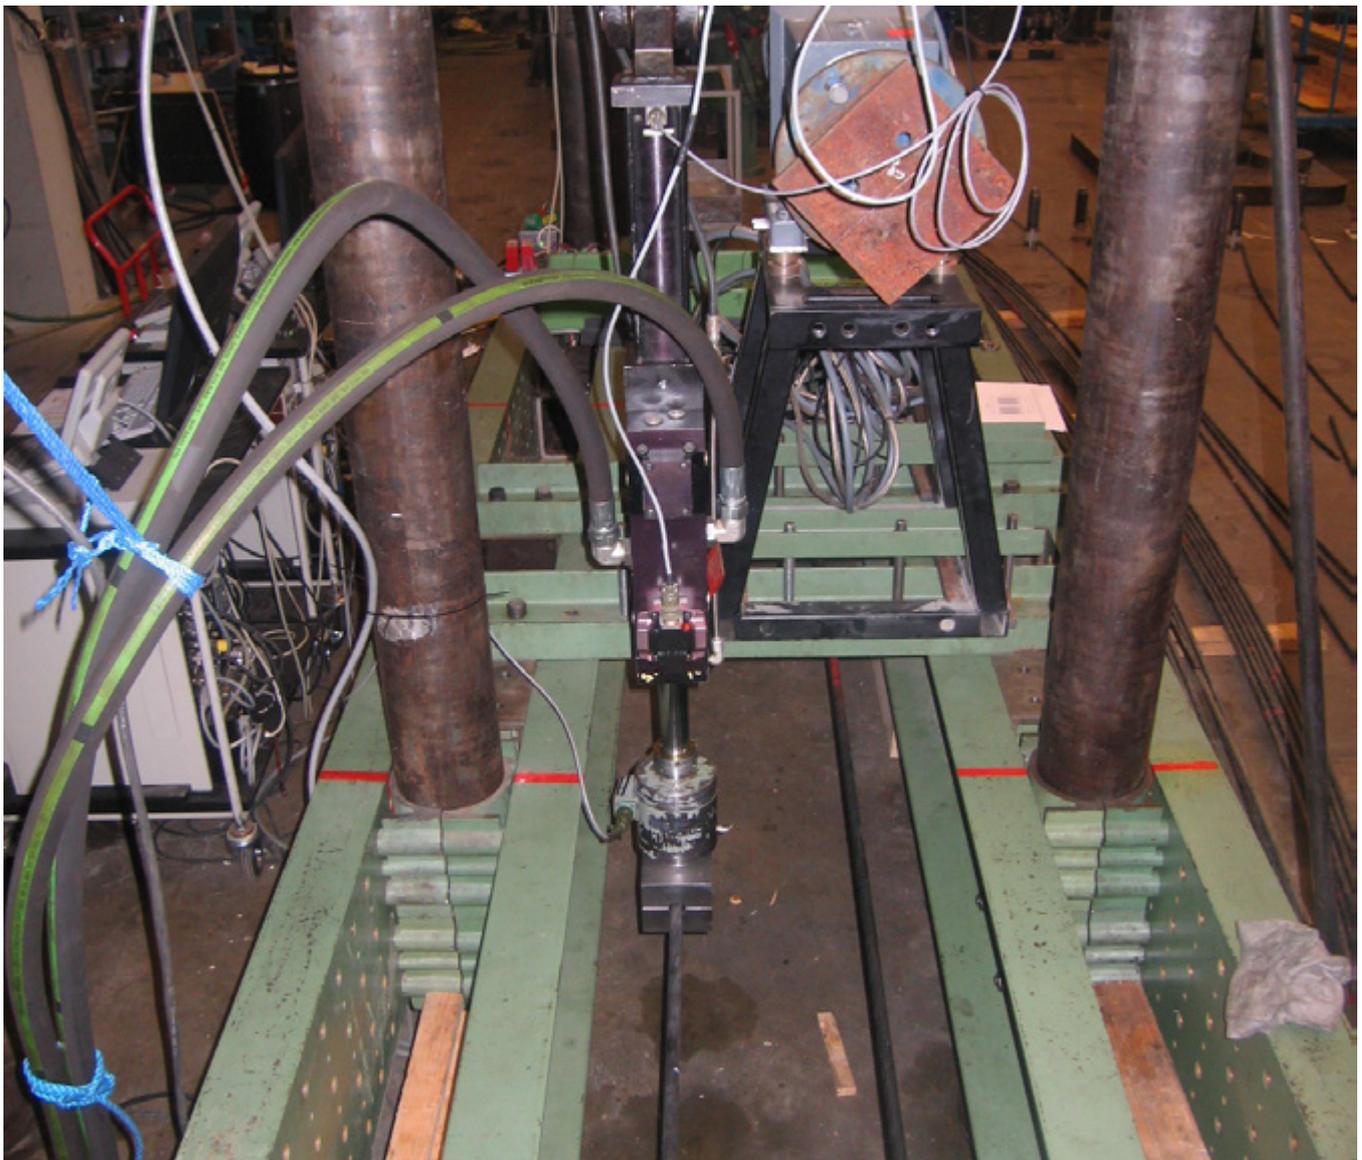

- Application of 10 million load cycles
- Stress range of 200N/mm²
- Upper load level of 45% GUTS
- Anchorages inclined by 10mrad

MONOSTRAND FATIGUE TESTING UNDER REVERSED CYCLIC FLEXURAL LOADING

A series of *bending fatigue* tests on galvanized, waxed and PE-coated 7 wire strands 0.62" with an ultimate tensile strength of 1,860N/mm² were successfully performed. They proved that the standard protective measures of the sealing unit within the DYNA Grip® Anchorage are effective for fatigue bending *without* the additional use of a guide deviator.

- Application of 2 million load cycles
- Different upper load levels varying from 45% to 60% GUTS
- Static inclination at the anchorage between 0.6° and 3.0°
- Additional angular deviation at the center of the strand between ± 10mrad and ± 35mrad

LEAK TIGHTNESS TEST

DSI anchorages are fully resistant to any infiltration of water. Tested according to PTI requirements:

- Subsequent to fatigue testing
- For 96 hours
- With a 3m water head

And tested according to fib and Setra requirements with:

- Up to 3m water head
- Several longitudinal and transverse load cycles
- Temperature cycle 20°C – 70°C

Cable Installation

DSI has developed various methods to optimize and simplify cable installation procedures depending on site specific space and time constraints.

If required, the complete cable can also be preassembled on the ground first.

- The outer sheathing is welded to its required length directly on site using heated tool welding and is then lifted into an inclined position
- Strands are uncoiled either from wooden reels or are provided reel-less. They are installed and stressed one by one using lightweight equipment
- Strand installation is performed using small winches or pushing devices
- Hardware configuration can be adjusted to site conditions to ensure a fast, customized solution that minimizes costs and cycle times
- Afterwards, strands are installed into the sheathing, and the complete cable is lifted into its final position
- Subsequently, all strands are stressed

Stressing

DYWIDAG stressing equipment is designed to ensure an economic and convenient installation process.

CONTEN STRESSING

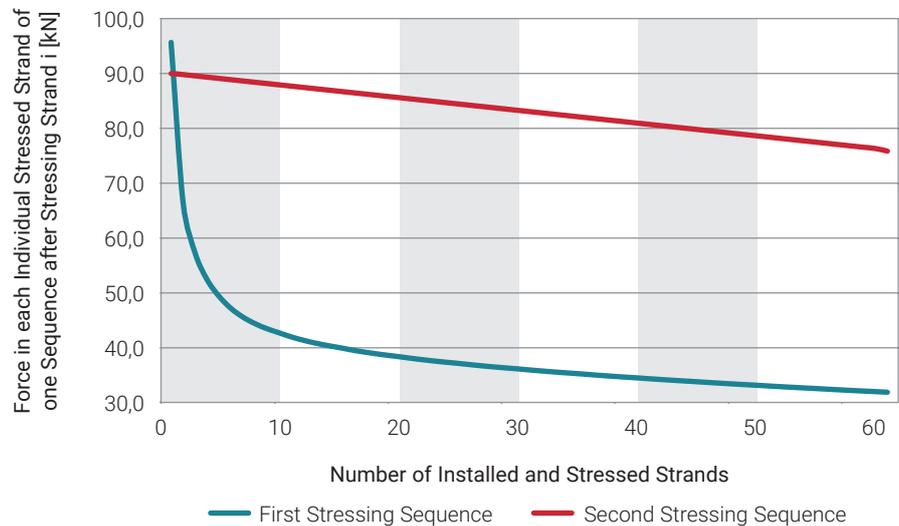

The patented (EP2307637 B1; US8702066 B2) ConTen System uses a monojack that is hydraulically coupled with a control unit. The system is applicable both for DYNA Grip® and DYNA Bond® Stay Cable Systems.

In case of very short strand elongation values or if the cable force needs to be adjusted, retensioning or releasing of the complete cable is possible by turning the ring nut. Special compact gradient jacks are available for this purpose

- Gradient jacks may be moved fully assembled or disassembled into their main components so that they fit even through small openings
- The same economic type of hydraulic pump can be used for both stressing systems. The pump is light, robust and has proven its reliability in many stay cable projects

- A special calculation method – developed by DSI – determines the force for the first strand and the corresponding forces for all subsequent strands
- This allows monitoring the stressing operation up to the required final cable force
- Every single strand is stressed individually
- Equal forces are achieved in all strands within one cable at the end of the stressing operation
- Influences of temperature and load changes during stressing are automatically eliminated

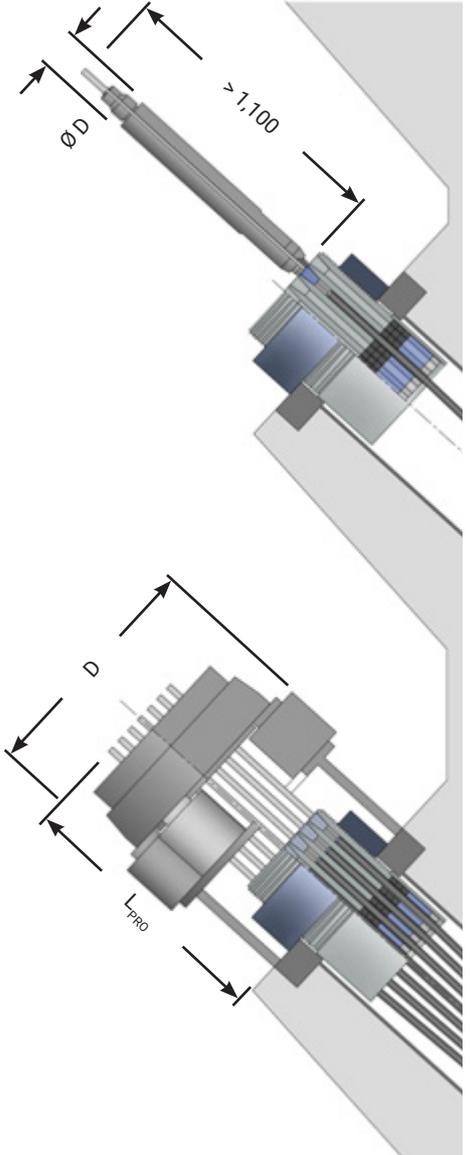

CHANGE OF STRAND FORCE DEPENDING ON THE NUMBER OF STRESSED STRANDS

Standard Hydraulic Pump

** For multistrand jacks for DYNA Bond®, please contact DSI

DYNA Force® Elasto-Magnetic Sensor

This system has been developed to measure or monitor forces within single strands of a stay cable during the construction progress as well as during the entire service life.

FUNCTIONAL PRINCIPLE

- The permeability of steel to a magnetic field changes with the stress level in the steel
- By measuring the change in a magnetic field, the magnitude of the stress in the steel element is obtained
- Data is gathered and elected by special system components
- Data can be handled using a conventional computer

SYSTEM COMPONENTS

- Portable Power Stress Unit
- Sensor with lead wire
- Multiplexer Box for connecting more than one sensor to the Power stress Unit at the same time
- Automated measurement on several sensors through multiplexer
- Transfer of data by WLAN connection or cellular wireless connection

SYSTEM ADVANTAGES IN COMPARISON TO OTHER MEASURING SYSTEMS

- The system cannot be overloaded
- Maintenance free
- No direct contact between the sensor and the strand/bar
- Resistant against dust and humidity
- Up to 2% of measurement accuracy

QUALITY ASSURANCE

- All DYNA Force® Sensors are professionally made in a quality controlled facility
- Every DYNA Force® Sensor is tested and individually packed and numbered at the DSI facility before it is sent to the job site

PRACTICAL APPLICATIONS

- When a DYNA Force® Sensor is installed on a strand, the force in it may be obtained directly by merely attaching the leads from the sensor to a portable Power Stress Unit
- No other equipment is needed
- DYNA Force® Sensors have been used in many bridge and building structures for the past several years
- Applicable not only for long-term monitoring, but also for supervision during the construction phase

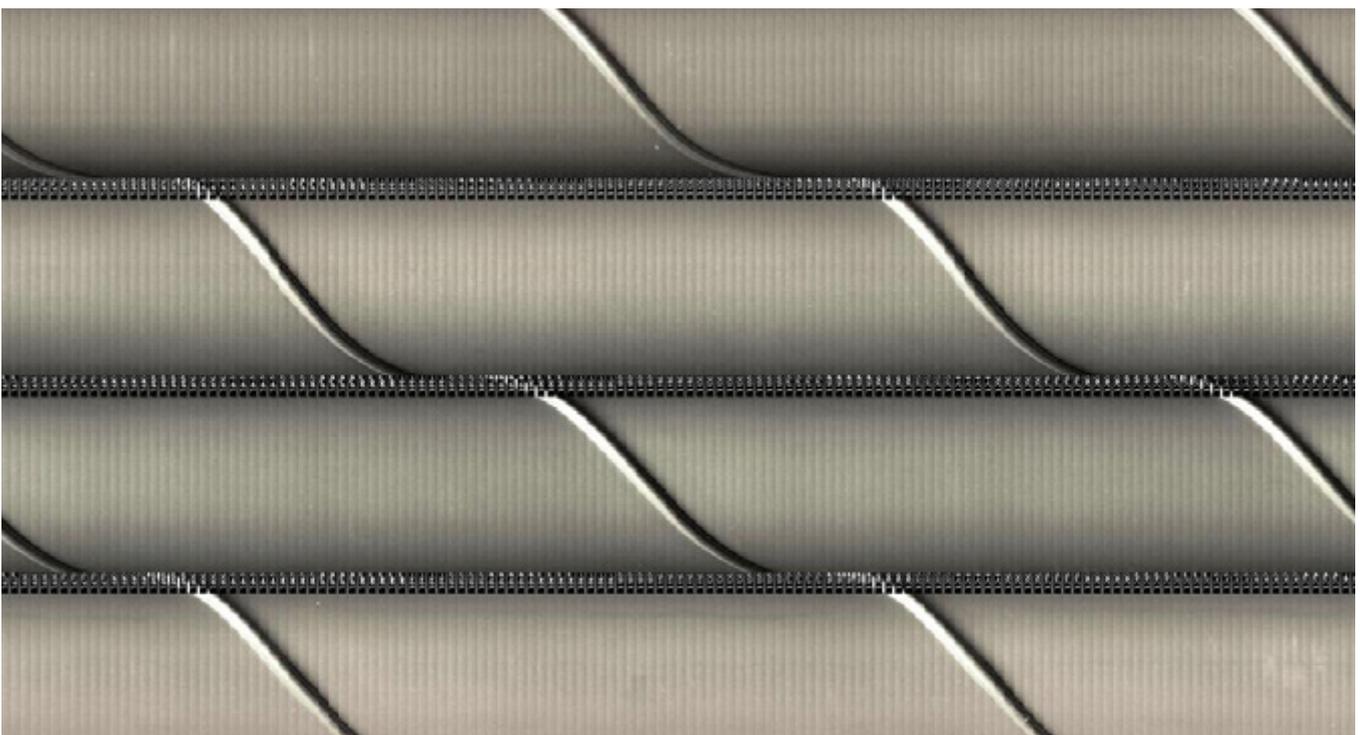

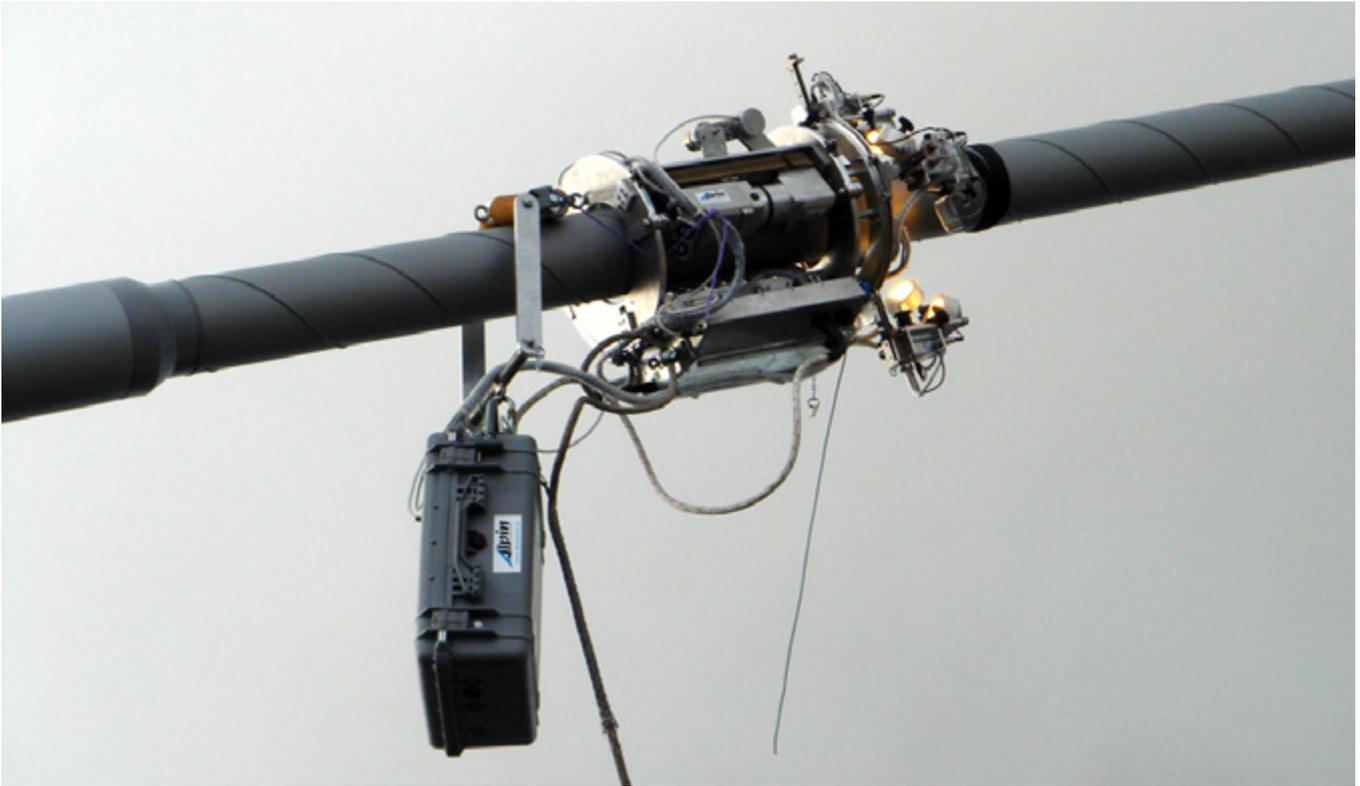

Cable Inspection

VISUAL INSPECTION

Visual inspection is a key measure during cable maintenance and inspection.

- DYWIDAG visual inspection keeps traffic disturbances to a minimum
- Cameras are placed on an automotive cable robot that moves along the outer surface of the cable sheathing
- Cable surface is checked for damages or color changes
- Possible defects can be detected quickly
- Afterwards, detailed examinations can be limited to critical spots

VIBRATION MEASUREMENT

Cable forces and cable damping values are very important both during and after construction as well as for monitoring. DSI offers vibration measurement for tension members to quickly and efficiently determine both cable forces and damping values.

- A 3-dimensional accelerometer, placed on the cable, registers its movements
- Measurement at one cable only takes a few minutes
- Each cable has an individual vibration characteristic depending on cable force, dimensions, the type of anchorage and on possible cable supports
- Eigenfrequencies and eigenmodes correspond to the vibration characteristics and can be calculated from the vibration measurement
- The obtained cable eigenfrequencies are used to calculate tensioning forces
- Damping values can be calculated by determining the decay of vibration amplitudes

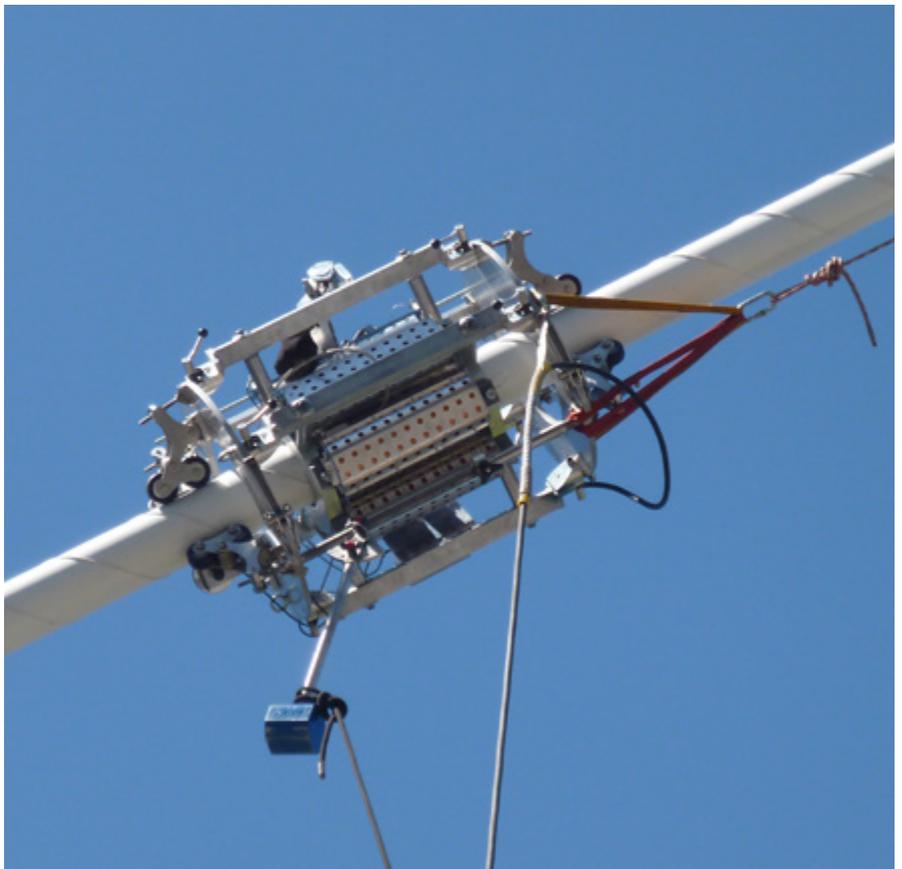

MAGNETIC FLUX LEAKAGE INSPECTION

Magnetic flux leakage inspection is a non-destructive testing method that detects changing magnetic properties. DSI uses this method to determine corrosion, breaks or cuts to strands.

Magnetic flux leakage inspection is a very economic and fast testing procedure:

- The equipment can be adapted to fit different pipe diameters
- Only the deck anchorage needs to be accessible for mounting the equipment. The measuring equipment is moved by hoists and winches in the free cable length, thus minimizing traffic disturbances
- The whole strand bundle can be magnetized, which even allows checking strands on the inside

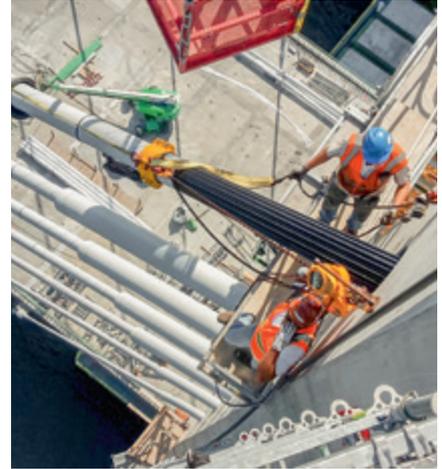

There is no need to remove HDPE sheathing: The equipment moves along the pipes, and the magnetic field permeates the HDPE sheathing.
